# Lambda Calculus and Combinatory Logic 

Lecture notes<br>by<br>Thomas Piecha

These notes are almost completely based on Peter Schroeder-Heister's course
"Lambda-Kalkül und Kombinatorische Logik" (summer semester 1997) and the typeset notes produced by Michael Arndt as well as my notes taken in that course.

Some corrections and additions were made.

Winter semester 2017/18
University of Tübingen
Department of Computer Science and Department of Philosophy

## Vorwort 1997

Dies ist ein Skriptum zu einer Vorlesung, die ich zuletzt im Sommersemester 1997 gehalten habe. In den ersten beiden Teilen orientiert es sich im wesentlichen am klassischen Lehrbuch von Hindley und Seldin, in den letzten beiden Teilen an Barendregts Kapitel über den getypten $\lambda$-Kalkül im Handbook of Logic in Computer Science (Band II). Das Skriptum soll zur Orientierung über das technische Gerüst des Themas dienen. Dementsprechend ist es nicht bis in alle Einzelheiten ausgearbeitet. So wurde auf Stilfragen wenig Rücksicht genommen. Auch wurden elementare, aber langwierige Beweise häufig weggelassen. Erläuternde Passagen zu Sinn und Zweck des $\lambda$-Kalküls sowie einzelner Begriffsbildungen sind ebenfalls nicht aufgezeichnet. Hierzu seien Leser auf die genannten Texte verwiesen.
Ich danke Michael Arndt für die Erstellung des Skriptums. Frau Natali Alt und Herrn Reinhard Kahle danke ich für eine kritische Durchsicht des Textes. Alle verbleibenden inhaltlichen Fehler gehen natürlich zu meinen Lasten.

Peter Schroeder-Heister

## Vorwort 2016

Bei dieser aktualisierten Fassung des Skripts konnte ich auch auf die zweite Auflage des Lehrbuchs von Hindley und Seldin zurückgreifen:
J. Roger Hindley und Jonathan P. Seldin: Lambda-Calculus and Combinators, an Introduction, Cambridge University Press, 2008 (reprinted 2010).

Es wurde wieder darauf verzichtet, die Verwendung dieser und anderer Quellen (siehe Literaturverzeichnis) im Einzelnen immer kenntlich zu machen.

Thomas Piecha

Preface 2017/18
This is a translation of the 2016 version, including some further corrections and additions.

## 1 The untyped $\lambda$-calculus

The $\lambda$-calculus is a formal system in which the formation and application of functions can be expressed. We first consider the untyped version of $\lambda$-calculus, where functions are not restricted to data types.

## Motivation of the syntax

The syntax of $\lambda$-calculus will allow us to systematically form an expression for a function of a variable $x$ from an expression containing $x$, and likewise for any other variables. Consider the expression " $x-y$ ", which can be taken as a definition of either a function $f$ of $x$ or of a function $g$ of $y$, usually written as follows:

$$
f(x)=x-y \quad g(y)=x-y
$$

or

$$
f: x \mapsto x-y \quad g: y \mapsto x-y
$$

Using $\lambda$-notation, one can write instead:

$$
f=\lambda x \cdot x-y \quad g=\lambda y \cdot x-y
$$

Equations like

$$
f(0)=0-y \quad \text { and } \quad f(1)=1-y
$$

are then written as

$$
(\lambda x . x-y)(0)=0-y \quad \text { and } \quad(\lambda x . x-y)(1)=1-y
$$

respectively. For functions of two variables like e.g.

$$
h(x, y)=x-y \quad k(y, x)=x-y
$$

one can write

$$
h=\lambda x y \cdot x-y \quad k=\lambda y x \cdot x-y
$$

One can avoid such expressions for functions of several variables by allowing for functions of functions. For example, instead of the two-place function $h$, one can then use the following one-place function $h^{\prime}$ :

$$
h^{\prime}=\lambda x \cdot(\lambda y \cdot x-y)
$$

For each number $a$ we have

$$
h^{\prime}(a)=\lambda y \cdot a-y
$$

and thus for each pair of numbers $a, b$ :

$$
\left(h^{\prime}(a)\right)(b)=(\lambda y \cdot a-y)(b)=a-b=h(a, b)
$$

It is therefore sufficient to consider only one-place functions. (The transition from manyplace to one-place functions is called "currying" (after H. B. Curry) or "schönfinkeling" (after M. Schönfinkel).)
For the functions $h$ and $h^{\prime}$ we have here assumed that the variables $x$ and $y$ range over numbers, i.e., $x$ and $y$ refer to objects of the type "number". To completely specify a function one would also have to declare the type of objects the function can return. We will consider types later, when we study typed $\lambda$-calculus. In untyped $\lambda$-calculus, a function like e.g. ( $\lambda x . x)$ can be seen as a generic identity function; applied to an arbitrary object it simply returns the same object.

## On semantics

The semantics of $\lambda$-calculus is operational. If $M$ can be interpreted as a function, then $(M N)$ is the result of an application of $M$ to the argument $N$, in case the result exists. A term ( $\lambda x . M)$ is interpreted as a function, whose value for an argument $N$ is calculated by substituting $N$ for $x$ in $M$.

Example. The term $(\lambda x . x(x y))$ is interpreted as the operation of applying a function twice to an object $y$. Thus, for any term $N,(\lambda x . x(x y)) N=N(N y)$ in the sense that the left and the right term have the same interpretation.

### 1.1 Syntax and operational semantics

Let an infinite series of variables be given (in a fixed order).
Metalinguistic symbols for variables are: $u, v, w, x, y, z, x_{1}, x_{2}, x_{3}, \ldots$ (Different symbols denote different variables, unless stated otherwise.)

There are two variants of untyped $\lambda$-calculus:

- pure $\lambda$-calculus: no constants given.
- applied $\lambda$-calculus: finite or infinite set of constants given.
(The first two chapters deal only with untyped $\lambda$-calculus. We therefore omit the word "untyped".)

Definition $1.1 \lambda$-terms (short: terms) are defined as follows:

1. All variables and constants are $\lambda$-terms (atoms).
2. If $M$ and $N$ are $\lambda$-terms, then $(M N)$ is a $\lambda$-term (application), having $M$ and $N$ as immediate subterms.
3. If $M$ is a $\lambda$-term, then $(\lambda x . M)$ is a $\lambda$-term (abstraction), having $x$ and $M$ as immediate subterms.
$\lambda$-terms
atoms
application

Remark: Thus $\lambda$ and e.g. $\lambda x$ are not $\lambda$-terms.

## Further notions:

- The length of a term $M$ is the number of occurrences of atoms in $M$.
- Subterms of a term are the term itself, as well as the subterms of its immediate subterms. All subterms of a term except itself are its proper subterms.
- We write $M[P]$, if $P$ occurs as subterm at a certain position in $M$.
- In the context of $M[P]$ the expression $M[Q]$ means that one has replaced the occurrence of $P$ by $Q$.
- The occurrence of a variable $x$ in a term $M$ is bound, if it belongs to a subterm $\lambda x . P$ of $M$, otherwise it is free.
- If $x$ has a free occurrence in $M$, then $x$ is called a free variable of $M$. The set of free variables of a term $M$ is called $\mathrm{FV}(M)$.
- $M$ is called closed, if $\mathrm{FV}(M)=\emptyset$, otherwise open.
- A closed term without constants is called combinator.
- Metalinguistic variables: $M, N, P, Q, R, S, T, \ldots$ for $\lambda$-terms; $a, b, c, \ldots$ for atoms.
- $\lambda$-terms can be abbreviated by omitting parentheses as follows, as long as no ambiguities can arise:
length
subterm
bound
free
closed/open
combinator
convention on parentheses
- Outermost parentheses can be omitted.
- We use association to the left, i.e. $M N P Q$ stands for $((M N) P) Q$.
- $\lambda x . M N$ stands for $(\lambda x$. $(M N))$.
- $\lambda x_{1} x_{2} \ldots x_{n} \cdot M$ stands for $\left(\lambda x_{1} \cdot\left(\lambda x_{2} \cdot\left(\ldots\left(\lambda x_{n} \cdot M\right)\right)\right)\right)$.
- $M \bumpeq N$ denotes the syntactic identity of $M$ and $N$.
$M: \bumpeq N$ says that $M$ and $N$ are syntactically identical by definition; $M$ is the definiendum, $N$ is the definiens.

Remark. The terms of pure $\lambda$-calculus can be characterised by the following context-free grammar, if variables have the form $v_{0 \ldots . .0}$ :

- Terminals: $\left\{\lambda, .,(),, v_{0},{ }_{0}\right\}$
- Non-terminals: $\{T, V\}$
- Start symbol: $T$
- Productions: $T \longrightarrow V|(T T)|(\lambda V . T)$
$V \longrightarrow v_{0} \mid V_{0}$

## Examples.

- $\left(\lambda v_{0} \cdot\left(v_{0} v_{00}\right)\right)$ is a $\lambda$-term of length 3 .

Immediate subterms: $v_{0}$ and $\left(v_{0} v_{00}\right)$
The term is open, since $v_{00}$ occurs free. The variable $v_{0}$ occurs bound twice.
Abbreviated: $\lambda v_{0} . v_{0} v_{00}$

- In $\lambda x y . x y$ the term $x y$ occurs once. It is $\lambda x y . x y \bumpeq(\lambda x .(\lambda y .(x y)))$.
- In $x(u v)(\lambda u \cdot v(u v)) u v$ the term $u v$ occurs twice.

It is $x(u v)(\lambda u \cdot v(u v)) u v \bumpeq((((x(u v))(\lambda u .(v(u v)))) u) v)$.

- In $\lambda u . u v$ the term $\lambda u . u$ does not occur.

It is $\lambda u . u \bumpeq(\lambda u . u)$ and $\lambda u . u v \bumpeq(\lambda u .(u v))$.
Examples. Let $x, y, z$ be any distinct variables. Then the following are $\lambda$-terms:

- $(\lambda x .(x y)) \quad$ (cp. last example above)
- $((\lambda y . y)(\lambda x .(x y)))$
$-(x(\lambda x .(\lambda x . x)))$
This term has the form $(M N)$, where $N$ has two occurrences of $\lambda x$. (This is permitted, but not recommended.)
- $(\lambda x .(y z))$

This term has the form $(\lambda x . M)$, where $x$ does not occur in $M$. This is called vacuous abstraction. Such terms stand for constant functions (i.e., for functions having for all inputs the same output).

Examples. On parentheses:
$-x y z(y x) \bumpeq(((x y) z)(y x))$
$-\lambda x . u x y \bumpeq(\lambda x .((u x) y))$
$-\lambda u . u(\lambda x . y) \bumpeq(\lambda u .(u(\lambda x . y)))$
$-(\lambda u . v u u) z y \bumpeq(((\lambda u .((v u) u)) z) y)$
$-u x(y z)(\lambda v . v y) \bumpeq(((u x)(y z))(\lambda v .(v y)))$
$-(\lambda x y z . x z(y z)) u v w \bumpeq((((\lambda x \cdot(\lambda y \cdot(\lambda z \cdot((x z)(y z))))) u) v) w)$
Examples. The following closed $\lambda$-terms (combinators) get a name:
$-\mathbf{I}: \bumpeq \lambda x . x$
$-\mathbf{K}: \bumpeq \lambda x y \cdot x$
$-\mathbf{S}: \bumpeq \lambda x y z . x z(y z)$

Definition 1.2 For any $M, N, x$, we define the substitution $M[N / x]$ by induction on $M$ to be the result of replacing every free occurrence of $x$ in $M$ by $N$, and changing bound variables to avoid clashes:

1. $x[N / x]: \bumpeq N$,
2. $a[N / x]: \bumpeq a$, if $x \neq a$,
3. $(P Q)[N / x]: \bumpeq(P[N / x] Q[N / x])$,
4. $(\lambda x . P)[N / x]: \bumpeq \lambda x . P$,
5. $(\lambda y . P)[N / x]: \bumpeq \lambda y . P[N / x]$, if $x \neq y$ and not: $y \in \mathrm{FV}(N)$ and $x \in \mathrm{FV}(P)$,
6. $(\lambda y \cdot P)[N / x]: \bumpeq \lambda z \cdot P[z / y][N / x]$, if $x \neq y$ and $y \in \mathrm{FV}(N)$ and $x \in \mathrm{FV}(P)$, where $z$ is the first variable (in the enumeration of all variables) with $z \notin \mathrm{FV}(N P)$.

## Examples.

$-(\lambda x . z y)[(u v) / x] \bumpeq \lambda x . z y \quad$ (Def. 1.2, 4)
$-(\lambda y . x)[y / x] \bumpeq \lambda z . y \quad$ (Def. 1.2, 6, for $z$ being the first variable distinct from $x$ and $y$ )
$-(\lambda y \cdot x(\lambda x \cdot x))[(\lambda y \cdot x y) / x] \bumpeq \lambda y .(\lambda y \cdot x y)(\lambda x \cdot x)$, since

$$
\begin{align*}
(\lambda y \cdot x(\lambda x \cdot x))[(\lambda y \cdot x y) / x] & \bumpeq(\lambda y \cdot(x(\lambda x \cdot x)))[(\lambda y \cdot x y) / x] & & \text { (parentheses) } \\
& \bumpeq(\lambda y \cdot(x(\lambda x \cdot x))[(\lambda y \cdot x y) / x]) & & (\text { Def. 1.2, 5) } \\
& \bumpeq(\lambda y \cdot(x[(\lambda y \cdot x y) / x](\lambda x \cdot x)[(\lambda y \cdot x y) / x])) & & (\text { Def. 1.2, 3) } \\
& \bumpeq(\lambda y \cdot((\lambda y \cdot x y)(\lambda x \cdot x)[(\lambda y \cdot x y) / x])) & & (\text { Def. 1.2, 1) } \\
& \bumpeq(\lambda y \cdot((\lambda y \cdot x y)(\lambda x \cdot x))) & & \text { (Def. 1.2, 4) }  \tag{Def.1.2,4}\\
& \bumpeq \lambda y \cdot(\lambda y \cdot x y)(\lambda x \cdot x) & & \text { (parentheses) }
\end{align*}
$$

## Definition 1.3

- We define renaming of bound variables as follows:

$$
\text { If } y \notin \mathrm{FV}(M) \text {, then let } P[\lambda x \cdot M] \equiv_{1 \alpha} P[\lambda y \cdot M[y / x]]
$$

- Then $\alpha$-conversion (or congruence) is defined as follows:

$$
\text { Let } P \equiv_{\alpha} Q \text {, if } P \bumpeq P_{1} \equiv_{1 \alpha} P_{2} \equiv_{1 \alpha} \cdots \equiv_{1 \alpha} P_{n} \bumpeq Q .
$$

(If $P \equiv{ }_{\alpha} Q$, we say " $P$ is congruent to $Q$ " or " $P \alpha$-converts to $Q$ ".)
Example. It is $\lambda x y \cdot x(x y) \equiv{ }_{\alpha} \lambda u v \cdot u(u v)$ :

$$
\begin{aligned}
\lambda x y \cdot x(x y) \bumpeq \lambda x \cdot(\lambda y \cdot x(x y)) & \equiv \equiv_{1 \alpha} \lambda x \cdot(\lambda v \cdot x(x v)) \\
& \equiv_{1 \alpha} \lambda u \cdot(\lambda v \cdot u(u v)) \bumpeq \lambda u v \cdot u(u v)
\end{aligned}
$$

Lemma 1.4 For all $\lambda$-terms $M, N$ and all variables $x$ we have:

1. $M[x / x] \bumpeq M$.

$$
3-\cos -2
$$

substitution

[^0]renaming of bound variables
$\alpha$-conversion congruence
2. If $x \notin \operatorname{FV}(M)$, then $M[N / x] \bumpeq M$.
3. If $x \in \mathrm{FV}(M)$, then $\mathrm{FV}(M[N / x])=\mathrm{FV}(N) \cup(\mathrm{FV}(M) \backslash\{x\})$.

Proof. Direct application of Definition 1.2.
QED
Lemma 1.5 Let no variable bound in the $\lambda$-term $M$ be free in $\lambda$-terms $P, Q$ and $z$. Then the following holds:

1. If $z \notin \mathrm{FV}(M)$, then $M[z / x][P / z] \bumpeq M[P / x]$.
2. If $z \notin \operatorname{FV}(M)$, then $M[z / x][x / z] \bumpeq M$.
3. $M[Q / x][P / x] \bumpeq M[(Q[P / x]) / x]$
4. If $y \notin \mathrm{FV}(P)$, then $M[Q / y][P / x] \bumpeq M[P / x][(Q[P / x]) / y]$.
5. If $y \notin \mathrm{FV}(P)$ and $x \notin \mathrm{FV}(Q)$, then $M[Q / y][P / x] \bumpeq M[P / x][Q / y]$.

Proof. The restriction on bound variables in $M$ excludes substitutions according to Definition 1.2 (6).
Proofs of (1), (3) and (4) are by term induction on $M$.
(2) follows from (1) and Lemma 1.4 (1); (5) follows from (4) and Lemma 1.4 (2). QED

Remark. If in Lemma 1.5 the restriction on variables bound in $M$ is lifted and $\bumpeq$ is replaced by $\equiv_{\alpha}$, then the resulting statements (1)-(5) hold as well.

## Lemma 1.6

1. If $P \equiv{ }_{\alpha} Q$, then $\mathrm{FV}(P)=\mathrm{FV}(Q)$.
2. For each term $P$ and all variables $x_{1}, \ldots, x_{n}$ there exists a term $P^{\prime}$ with $P \equiv{ }_{\alpha} P^{\prime}$, where no variable $x_{1}, \ldots, x_{n}$ occurs bound in $P^{\prime}$.
3. $\equiv_{\alpha}$ is an equivalence relation. That is, we have:

Reflexivity: $P \equiv{ }_{\alpha} P$.
Symmetry: If $P \equiv{ }_{\alpha} Q$, then $Q \equiv{ }_{\alpha} P$.
Transitivity: If $P \equiv_{\alpha} Q$ and $Q \equiv_{\alpha} M$, then $P \equiv{ }_{\alpha} M$.
Proof. Exercise.
QED
Lemma 1.7 (Congruence of $\equiv_{\alpha}$ )
If $M \equiv{ }_{\alpha} M^{\prime}$ and $N \equiv{ }_{\alpha} N^{\prime}$, then $M[N / x] \equiv{ }_{\alpha} M^{\prime}\left[N^{\prime} / x\right]$.
Proof. See Hindley \& Seldin (2008), appendix A1. QED

## Remarks.

1. Substitution is well-behaved with respect to $\alpha$-conversion. The result of a substitution where $N$ has been $\alpha$-converted to a term $N^{\prime}$ differs only by congruence from the result for a substitution with $N$.
2. By using $\alpha$-conversion one can always separate variables in a term first, to avoid more complicated substitutions later.
3. Any two congruent terms will have identical interpretations.

Remark. In the following, we write $P \stackrel{\triangleright_{1 \beta}}{\equiv \equiv_{1 \alpha}} Q$ for " $P \triangleright_{1 \beta} Q$ or $P \equiv_{1 \alpha} Q$ " and $P \underset{\triangleright_{1 \beta}}{\stackrel{\Xi_{1 \beta}}{\triangleright_{1 \beta}} Q} Q$ for " $P \equiv_{1_{\alpha}} Q$ or $P \triangleright_{1 \beta} Q$ or $Q \triangleright_{1 \beta} P$ ", etc. (Note that $P \triangleleft_{1 \beta} Q$ just means $Q \triangleright_{1 \beta} P$.)

## Definition 1.8

- A term of the form $(\lambda x . M) N$ is called $\beta$-redex (short: redex, from reducible expression), and the corresponding term $M[N / x]$ is its contractum.
- The operation of $\beta$-contraction is defined by:

$$
P[\underbrace{(\lambda x . M) N}_{\beta \text {-redex }}] \triangleright_{1 \beta} P[\underbrace{M[N / x]}_{\text {contractum }}] .
$$

- If for a term $P$ there exists a (possibly empty) finite series of $\beta$-contractions and renamings of bound variables ending in a term $Q$, i.e. if

$$
P \bumpeq P_{1} \xlongequal{\unrhd_{1 \beta}} P_{2} \xlongequal[\unrhd_{1 \beta}]{ŋ_{1 \alpha}} \cdots \underset{l_{1 \alpha}}{\unrhd_{1 \beta}} P_{n} \bumpeq Q
$$

then we say that $P \beta$-reduces to $Q$. Notation: $P \triangleright_{\beta} Q$.

- Two terms $P$ and $Q$ are called $\beta$-equal (or $\beta$-convertible), if the following holds:

$$
P \bumpeq P_{1} \underset{\nabla_{1 \beta}}{\Xi_{1 \beta}} P_{2} \underset{\triangleleft_{1 \beta}}{\Xi_{1 \beta}} \ldots \underset{\triangleleft_{1 \beta}}{\Xi_{1 \beta}} \ldots \underset{\triangleleft_{1 \beta}}{\Xi_{1 \beta}} P_{n} \bumpeq Q
$$

Notation: $P={ }_{\beta} Q$.

- For a (possibly empty) finite or infinite series of $\beta$-contractions

$$
P \bumpeq P_{1} \triangleright_{1 \beta} P_{2} \triangleright_{1 \beta} P_{3} \triangleright_{1 \beta} \ldots
$$

we call $\left(P_{1}, P_{2}, P_{3}, \ldots\right)$, or the given series itself, a $\beta$-reduction series of $P$.
Remark. By the two operations of $\alpha$-conversion (resp. renaming of bound variables) and $\beta$-contraction an operational semantics for $\lambda$-terms is given. The interpretation of $\lambda$-terms is defined by how they behave under these two operations.

## Definition 1.9

- $P$ is in $\beta$-normal form (short: $\beta$-nf ), if no $\beta$-redex occurs in $P$.
- If $P \triangleright_{\beta} Q$ holds, and $Q$ is in $\beta$-nf, then $Q$ is called $\beta$-normal form of $P$.
(We then also say that $P$ has $\beta$-normal form $Q$.)
- $P$ is called (weakly) normalisable, if there exists a $\beta$-normal form of $P$.
- $P$ is called strongly normalisable, if there is no infinite $\beta$-reduction series of $P$.

Remark. Note the difference between being in $\beta$-nf and having a $\beta$-nf. To see whether a term is in $\beta$-nf, one just has to check whether it contains a $\beta$-redex or not. To show that a term has a $\beta$-nf, one has to show that the term reduces to a $\beta$-nf (i.e., one has to show that there exists a finite $\beta$-reduction series ending with a term in $\beta$-nf).

## Examples.

$-(\lambda x . x) N \triangleright_{1 \beta} N$
$-(\lambda x . y) N \triangleright_{1 \beta} y$
$-(\lambda x . x(x y)) N \triangleright_{1 \beta} N(N y)$
$-(\lambda x .(\lambda y \cdot y x) z) v \triangleright_{1 \beta}(\lambda x . z x) v \triangleright_{1 \beta} z v$, and $z v$ is a $\beta$-normal form of $(\lambda x .(\lambda y . y x) z) v$.
$-\boldsymbol{\Omega}: \Omega(\lambda x . x x)(\lambda x . x x)$ does not have a $\beta$-normal form; $\boldsymbol{\Omega}$ is not in $\beta$-nf, and there is only an infinite $\beta$-reduction series: $(\lambda x . x x)(\lambda x . x x) \triangleright_{1 \beta}(\lambda x . x x)(\lambda x . x x) \triangleright_{1 \beta} \cdots$.
However, $\lambda$-terms containing the $\boldsymbol{\Omega}$-combinator can have a $\beta$-normal form. For example, the term $(\lambda x . y) \boldsymbol{\Omega}$ has $\beta$-nf $y$, since $(\lambda x . y) \boldsymbol{\Omega} \triangleright_{1 \beta} y$.
The term $(\lambda x . y) \boldsymbol{\Omega}$ is thus weakly normalisable; but it is not strongly normalisable, since there is an infinite $\beta$-reduction series: $(\lambda x . y) \boldsymbol{\Omega} \triangleright_{1 \beta}(\lambda x . y) \boldsymbol{\Omega} \triangleright_{1 \beta} \cdots$.
$-(\lambda x . x x y)(\lambda x . x x y) \triangleright_{1 \beta}(\lambda x . x x y)(\lambda x . x x y) y \triangleright_{1 \beta}(\lambda x . x x y)(\lambda x . x x y) y y \triangleright_{1 \beta} \cdots$.
The term $(\lambda x . x x y)(\lambda x . x x y)$ has no $\beta$-normal form.
The term $(\lambda u . v)((\lambda x . x x y)(\lambda x . x x y))$ is weakly but not strongly normalisable, having the $\beta$-normal form $v$.

Example. It is $(\lambda x y z \cdot x z y)(\lambda x y \cdot x)={ }_{\beta}(\lambda x y \cdot x)(\lambda x \cdot x)$, since

$$
\begin{array}{rlrl}
(\lambda x y z . x z y)(\lambda x y \cdot x) & \equiv{ }_{\alpha}(\lambda x y z \cdot x z y)(\lambda u v \cdot u) \quad \text { and } \quad(\lambda x y \cdot x)(\lambda x \cdot x) & \equiv_{\alpha}(\lambda x y \cdot x)(\lambda u \cdot u) \\
& \triangleright_{1 \beta} \lambda y z \cdot(\lambda u v \cdot u) z y & & \triangleright_{1 \beta} \lambda y \cdot(\lambda u \cdot u) \\
& \triangleright_{1 \beta} \lambda y z \cdot(\lambda v \cdot z) y & & \bumpeq \lambda y u \cdot u \\
& \triangleright_{1 \beta} \lambda y z . z & & \equiv_{\alpha} \lambda y z \cdot z
\end{array}
$$

## Lemma 1.10

1. If $P \triangleright_{\beta} Q$, then $\mathrm{FV}(P) \supseteq \mathrm{FV}(Q)$.
2. If $P \equiv_{\alpha} P^{\prime}, Q \equiv_{\alpha} Q^{\prime}$ and $P \triangleright_{\beta} Q$, then $P^{\prime} \triangleright_{\beta} Q^{\prime}$.
3. If $P \equiv{ }_{\alpha} P^{\prime}, Q \equiv{ }_{\alpha} Q^{\prime}$ and $P={ }_{\beta} Q$, then $P^{\prime}={ }_{\beta} Q^{\prime}$.
4. If $M \triangleright_{\beta} N$ and $P \triangleright_{\beta} Q$, then $P[M / x] \triangleright_{\beta} Q[N / x]$.
5. If $M={ }_{\beta} N$ and $P={ }_{\beta} Q$, then $P[M / x]={ }_{\beta} Q[N / x]$.

Proof. Exercise. QED

Lemma 1.11 The class of all $\beta$-normal forms can be defined inductively by the following rules:

1. All atoms are in $\beta$-normal form.
2. If $M_{1}, \ldots, M_{n}$ are in $\beta$-normal form, then $a M_{1} \ldots M_{n}$ is in $\beta$-normal form.
3. If $M$ is in $\beta$-normal form, then $\lambda x . M$ is in $\beta$-normal form.

That is, a $\beta$-normal form has the form $\lambda x_{1} \ldots x_{n} \cdot a M_{1} \ldots M_{m}$, where the $M_{i}$ have the same form.

Proof. We have to show that $M$ is in $\beta$-normal form iff $M$ can be produced by rules (1)-(3). The implication from right to left obvious.

It remains to show by induction on $M$ that if $M$ is in $\beta$-normal form, then $M$ can be produced by rules (1)-(3).
Let $M$ be in $\beta$-normal form.

- If $M \bumpeq a$, then $M$ can be produced according to rule (1).
- If $M \bumpeq(P Q)$, then (by the induction hypothesis) $P$ and $Q$ can be produced by applications of rules (1)-(3), where $P$ is not an abstraction. Thus $P \bumpeq a$ or $P \bumpeq a M_{1} \ldots M_{k}$. Therefore $M \bumpeq a Q$ or $M \bumpeq a M_{1} \ldots M_{k} Q$, which can be produced by rule (2).
- If $M \bumpeq \lambda x$. $P$, then (by the induction hypothesis) $P$ can be produced by (1)-(3), and by an application of rule (3) also $M$.

QED
Remark. Lemma 1.11 is about the class of all $\beta$-normal forms, not about the class of all $\lambda$-terms having a $\beta$-normal form.

Lemma 1.12 An arbitrary $\lambda$-term has either the form shown in Lemma 1.11, or it contains a subterm of the form $\lambda x_{1} \ldots x_{n} \cdot \underbrace{(\lambda x . M) N}_{\text {head redex }} M_{1} \ldots M_{m}$, for $m, n \geq 0$.

Proof. Consider the excluded subcase of $M \bumpeq(P Q)$ in the proof of Lemma 1.11. QED

## Theorem 1.13 (Church \& Rosser, 1936)

1. If $P \triangleright_{\beta} M$ and $P \triangleright_{\beta} N$, then there exists a term $T$ such that $M \triangleright_{\beta} T$ and $N \triangleright_{\beta} T$.
2. If $M={ }_{\beta} N$, then there exists a term $T$ such that $M \triangleright_{\beta} T$ and $N \triangleright_{\beta} T$.

## Remarks.

- Property (1) is called confluence of $\beta$-reduction. Diagrammatically:

- Property (2) indicates that two $\beta$-equal terms have the same interpretation, since there is always a term to which both reduce.

## Example.

Proof of Theorem 1.13 (2). By induction on the number of steps from $M$ to $N$.
Number of steps $=0:$ trivial.
Number of steps $=n+1:$ By the induction hypothesis we have

$$
P_{1} \triangleright_{\beta} T^{\prime}, \ldots, P_{n} \triangleright_{\beta} T^{\prime}
$$

for a term $T^{\prime}$. For the step from $n$ to $n+1$ the situation is the following:

$$
M \bumpeq P_{1}={ }_{\beta} \cdots={ }_{\beta} P_{n} \underset{T^{\prime}}{\substack{\overline{1}_{1 \alpha} \\ \triangle_{1 \beta}}} P_{n+1} \bumpeq N
$$

and we have to show:

$$
M \bumpeq P_{1}={ }_{\beta} \cdots={ }_{\beta} P_{n} \stackrel{\substack{\triangleright_{1 \beta} \\ \square_{1 \beta}}}{\doteq_{n+1} \bumpeq N}
$$

Case $1\left(\equiv_{1 \alpha}\right): T: \bumpeq T^{\prime}$, since $P_{n+1} \equiv_{1 \alpha} P_{n} \triangleright_{\beta} T^{\prime}$.
Case $2\left(\triangleleft_{1 \beta}\right): T: \bumpeq T^{\prime}$, since $P_{n+1} \triangleright_{1 \beta} P_{n} \triangleright_{\beta} T^{\prime}$.
Case $3\left(\triangleright_{1 \beta}\right)$ : Since $P_{n} \triangleright_{\beta} T^{\prime}$ and $P_{n} \triangleright_{1 \beta} P_{n+1}$, there exists according to Theorem 1.13 (1) a term $T$ such that $T^{\prime} \triangleright_{\beta} T$ and $P_{n+1} \triangleright_{\beta} T$ :

Thus $M \triangleright_{\beta} T\left(\right.$ since $\left.M={ }_{\beta} P_{n}\right)$ and $N \triangleright_{\beta} T$.
QED

For the proof of Theorem 1.13 (1) we need some more definitions and lemmas. The difficulty lies in the fact that confluence of $\triangleright_{\beta}$ cannot simply be proved by first proving confluence of $\triangleright_{1 \beta}$, that is, by proving

$$
\begin{equation*}
\text { if } P \triangleright_{1 \beta} M \text { and } P \triangleright_{1 \beta} N \text {, then } \exists T: M \triangleright_{1 \beta} T \text { and } N \triangleright_{1 \beta} T . \tag{*}
\end{equation*}
$$

Confluence of $\triangleright_{\beta}$ could be proved from $(*)$ by first proving the special case

$$
\text { if } P \triangleright_{1 \beta} M \text { and } P \triangleright_{\beta} N \text {, then } \exists T: M \triangleright_{\beta} T \text { and } N \triangleright_{1 \beta} T
$$

by induction on the length of the reduction series (including $\alpha$-conversions) from $P$ to $N$; schematically:

The general case could then be proved by a second induction on the length of the reduction series (again including $\alpha$-conversions) from $P$ to $M$ :

However, $(*)$ does not hold for all $\lambda$-terms. A counterexample is

$$
P \bumpeq(\lambda y \cdot u y y)(\mathbf{I} z) \quad(\text { where } \mathbf{I} \bumpeq \lambda x \cdot x)
$$

In this case $P \triangleright_{1 \beta} u(\mathbf{I} z)(\mathbf{I} z)$ and $P \triangleright_{1 \beta}(\lambda y . u y y) z \triangleright_{1 \beta} u z z$. But $u(\mathbf{I} z)(\mathbf{I} z)$ cannot be contracted to $u z z$, that is, $u(\mathbf{I} z)(\mathbf{I} z) \not \triangleright_{1 \beta} u z z$.
The term $u(\mathbf{I} z)(\mathbf{I} z)$ could be reduced to $u z z$ in one step by contracting the two nonoverlapping redexes $(\mathbf{I} z)$ and $(\mathbf{I} z)$ in parallel. One could thus try to prove confluence for a relation of parallel reduction, from which confluence of $\triangleright_{\beta}$ could be proved by two inductions as described for (*).
However, parallel reduction cannot simply be defined as simultaneous non-overlapping contractions, since confluence fails for such a relation as well. A counterexample can be given for the term $P \bumpeq\left(\lambda x . R_{1}\right) R_{2}$, where $R_{1} \bumpeq(\lambda y . x y z) w$ and $R_{2} \bumpeq(\lambda u . u) v$ are both redexes. The term $P$ contracts to $\left(\lambda y . R_{2} y z\right) w \bumpeq M$ by a (trivial) simultaneous non-overlapping contraction. By a simultaneous non-overlapping contraction of $R_{1}$ and $R_{2}$ in $P$ we get $(\lambda x . x w z) v \bumpeq N$, which can only be reduced to $N$ itself (by $\alpha$-conversion) or to $v w z \bumpeq T$ (by contraction). But it is not possible to reduce $M$ to either of those by using only simultaneous non-overlapping contractions. That is, we have the following situation (where arrows stand for simultaneous non-overlapping contractions):

Nevertheless, a notion of parallel reduction (called minimal complete development) can be given, for which confluence holds. We first define certain results of contraction.

Definition 1.14 Let $R$ and $S$ with $R \neq S$ be $\beta$-redexes in $P$, where $R \triangleright_{1 \beta} R^{\prime}$, changing $P$ to $P^{\prime}$.
The residual $\operatorname{Res}(S, R)$ of $S$ with respect to $R$ is a redex in $P^{\prime}$, defined as follows:

1. $R$ is a (proper) subterm of $S$. Then $\operatorname{Res}(S, R): \bumpeq S\left[R^{\prime}\right]$.
(That is, $S$ has the form $(\lambda x . M) N$ and $R$ is in $M$ or in $N . R \triangleright_{1 \beta} R^{\prime}$ changes $M$ to $M^{\prime}$ or $N$ to $N^{\prime}$, changing $S$ to $\left(\lambda x . M^{\prime}\right) N$ or $(\lambda x . M) N^{\prime}$ in $P^{\prime}$. Then $\operatorname{Res}(S, R)$ is either $\left(\lambda x . M^{\prime}\right) N$ or $\left.(\lambda x . M) N^{\prime}.\right)$
2. $R$ is not a subterm of $S$. Then $\operatorname{Res}(S, R): \bumpeq S$.
(That is, $R$ and $S$ do not overlap in $P$. Thus contracting $R$ does not change the redex $S$, and $S$ is the residual w.r.t. $R$ in $P^{\prime}$.)

Remark. Due to the way $\operatorname{Res}(S, R)$ will be used, some other possible cases besides (1) and (2) do not have to be considered.

Definition 1.15 Let $\mathcal{R}=\left\{R_{1}, \ldots, R_{n}\right\}$ be a set of redexes in $P$. A redex $R_{i}$ is called minimal, if no $R_{j}$ is a proper subterm of $R_{i}$.
$P \triangleright_{\mathrm{mcd}} Q$ (minimal complete development of $P$ to $Q$ ), if $Q$ is obtained from $P$ by the
residual
minimal
minimal complete development
following (non-deterministic) procedure:
(1) Choose a minimal element $R_{i}$ in $\mathcal{R}$.
(2) $\beta$-contract $R_{i}$ in $P: P \triangleright_{1 \beta} P^{\prime}$.
(3) Let $\mathcal{R}^{\prime}=\bigcup_{j \neq i} \operatorname{Res}\left(R_{j}, R_{i}\right) . \quad\left(\mathcal{R}^{\prime}\right.$ has thus $n-1$ elements.)
(4) If $\mathcal{R}^{\prime} \neq \emptyset$, then go to step (1) with $\mathcal{R}:=\mathcal{R}^{\prime}$ and $P: \bumpeq P^{\prime}$.
(5) If $\mathcal{R}^{\prime}=\emptyset$, then let $Q \equiv{ }_{\alpha} P^{\prime}$.
(If $P \triangleright_{\text {med }} Q$, we also say that $P$ mcd-reduces to $Q$.)

## Remarks.

1. The relation $\triangleright_{\text {mcd }}$ is defined relative to a chosen set $\mathcal{R}$ of redexes. For different sets $\mathcal{R}$ there are thus different relations $\triangleright_{\text {mcd }}$, and it would be more appropriate to make this distinction clear by naming them $\triangleright_{\text {mcd }}^{\mathcal{R}}$, for each of the respective sets of redexes $\mathcal{R}$. As this would only complicate the presentation, we assume instead that the set of redexes is always chosen adequately, namely in such a way that all redexes of a considered term are elements of $\mathcal{R}$.
2. The relation $\triangleright_{\text {mad }}$ is not transitive, as the following example shows:

$$
(\lambda x . x y)(\lambda z . z) \triangleright_{\operatorname{mcd}}(\lambda z . z) y \text { and }(\lambda z . z) y \triangleright_{\operatorname{mcd}} y, \text { but }(\lambda x . x y)(\lambda z . z) \triangleright_{\operatorname{mcd}} y .
$$

Note that the redex $(\lambda z . z) y$ is not a residual of $(\lambda x . x y)(\lambda z . z)$.
3. For $\mathcal{R}=\emptyset$ we have $P \triangleright_{\text {mad }} P$.

Example. We consider again $P \bumpeq\left(\lambda x . R_{1}\right) R_{2}$, where $R_{1} \bumpeq(\lambda y . x y z) w$ and $R_{2} \bumpeq(\lambda u . u) v$. It is $P \triangleright_{\text {mod }} v w z \bumpeq Q$. The set of redexes in $P$ is $\mathcal{R}=\left\{\left(\lambda x . R_{1}\right) R_{2}, R_{1}, R_{2}\right\}$.
(1) Choose the minimal element $R_{1}$.
(2) $P \triangleright_{1 \beta}(\lambda x \cdot x w z) R_{2} \bumpeq P^{\prime}$
(3) $\mathcal{R}^{\prime}=\left\{\operatorname{Res}\left(P, R_{1}\right), \operatorname{Res}\left(R_{2}, R_{1}\right)\right\}=\left\{P^{\prime}, R_{2}\right\}$
(4) $\mathcal{R}^{\prime} \neq \emptyset$
(1) Choose the minimal element $R_{2}$.
(2) $P^{\prime} \triangleright_{1 \beta}(\lambda x . x w z) v \bumpeq P^{\prime \prime}$
(3) $\mathcal{R}^{\prime \prime}=\left\{\operatorname{Res}\left(P^{\prime}, R_{2}\right)\right\}=\left\{P^{\prime \prime}\right\}$
(4) $\mathcal{R}^{\prime \prime} \neq \emptyset$
(1) Choose the minimal element $P^{\prime \prime}$.
(2) $P^{\prime \prime} \triangleright_{1 \beta} v w z \bumpeq P^{\prime \prime \prime}$
(3) $\mathcal{R}^{\prime \prime \prime}=\emptyset$
(5) Let $Q \equiv{ }_{\alpha} P^{\prime \prime \prime}$.

Lemma 1.16 (Preservation of $\triangleright_{\text {med }}$ by $\equiv_{\alpha}$ )
If $P \triangleright_{\operatorname{mcd}} Q$ and $P \equiv{ }_{\alpha} P^{\prime}$, then $P^{\prime} \triangleright_{\text {mad }} Q$.
Lemma 1.17 (Preservation of $\triangleright_{\text {med }}$ by substitution)
If $M \triangleright_{\mathrm{mcd}} M^{\prime}$ and $N \triangleright_{\mathrm{mcd}} N^{\prime}$, then $M[N / x] \triangleright_{\mathrm{mcd}} M^{\prime}\left[N^{\prime} / x\right]$.
Lemma 1.18 (Confluence of $\triangleright_{\text {mcd }}$ )
If $P \triangleright_{\mathrm{mcd}} Q$ and $P \triangleright_{\mathrm{mcd}} R$, then there exists a term $T$ such that $Q \triangleright_{\mathrm{mcd}} T$ and $R \triangleright_{\mathrm{mcd}} T$.
Proof. By Lemma 1.16 we can assume that the given mcd-reductions do not contain $\alpha$-steps. The proof is by induction on the structure of $P$.
Case 1: $P \bumpeq a$. Then $Q \bumpeq R \bumpeq P$. Let $T: \bumpeq P$.
Case 2: $P \bumpeq \lambda x . P_{1}$. Then all redexes in $P$ are in $P_{1}$, and since there are no $\alpha$-steps we have $Q \bumpeq \lambda x \cdot Q_{1}$ and $R \bumpeq \lambda x . R_{1}$, where $P_{1} \triangleright_{\text {mcd }} Q_{1}$ and $P_{1} \triangleright_{\text {mcd }} R_{1}$.
By the induction hypothesis there exists a term $T_{1}$ such that $Q_{1} \triangleright_{\text {mcd }} T_{1}$ and $R_{1} \triangleright_{\mathrm{mcd}} T_{1}$. Let $T: \bumpeq \lambda x . T_{1}$.

Case 3: $P \bumpeq\left(P_{1} P_{2}\right)$, and all redexes of $\mathcal{R}$ are in $P_{1}$ and $P_{2}$, that is, $P$ itself is not reduced. By the induction hypothesis there are terms $T_{1}$ and $T_{2}$ such that with
 and

holds.
Let $T: \bumpeq\left(T_{1} T_{2}\right)$.
Case 4: $P \bumpeq(\lambda x . M) N$, and the residual of $P$ is contracted in only one of the two given mcd-reductions; we assume it is contracted in $P \triangleright_{\text {mcd }} Q$.

Then $P \triangleright_{\text {mcd }} Q$ has the form

$$
P \bumpeq(\lambda x . M) N \triangleright_{\operatorname{mcd}}\left(\lambda x . M^{\prime}\right) N^{\prime} \triangleright_{1 \beta} M^{\prime}\left[N^{\prime} / x\right] \bumpeq Q
$$

(where $M \triangleright_{\text {mcd }} M^{\prime}$ and $N \triangleright_{\text {mcd }} N^{\prime}$ ).
The other given mcd-reduction $P \triangleright_{\mathrm{mcd}} R$ has the form

$$
P \bumpeq(\lambda x \cdot M) N \triangleright_{\text {mod }}\left(\lambda x \cdot M^{\prime \prime}\right) N^{\prime \prime} \bumpeq R
$$

(where $M \triangleright_{\text {med }} M^{\prime \prime}$ and $N \triangleright_{\text {mcd }} N^{\prime \prime}$ ).
By the induction hypothesis for $M$ and $N$ there exist terms $M^{+}$and $N^{+}$such that

and

Let $T: \bumpeq M^{+}\left[N^{+} / x\right]$. Then by Lemma 1.17:

$$
Q \bumpeq M^{\prime}\left[N^{\prime} / x\right] \triangleright_{\operatorname{mcd}} M^{+}\left[N^{+} / x\right]
$$

Furthermore, by first separating the $\alpha$-conversions in the mcd-reductions for $M^{\prime \prime}$ and $N^{\prime \prime}$ as follows

$$
M^{\prime \prime} \triangleright_{\mathrm{mcd}} M^{*} \equiv_{\alpha} M^{+} \quad N^{\prime \prime} \triangleright_{\mathrm{mcd}} N^{*} \equiv_{\alpha} N^{+}
$$

where we assume that $M^{\prime \prime} \triangleright_{\mathrm{mcd}} M^{*}$ and $N^{\prime \prime} \triangleright_{\mathrm{mcd}} N^{*}$ are without $\alpha$-steps, we obtain $R \triangleright_{\text {mcd }} T$ :

$$
R \bumpeq\left(\lambda x . M^{\prime \prime}\right) N^{\prime \prime} \triangleright_{\mathrm{mcd}}\left(\lambda x . M^{*}\right) N^{*} \triangleright_{1 \beta} M^{*}\left[N^{*} / x\right] \equiv_{\alpha} M^{+}\left[N^{+} / x\right]
$$

Case 5: $P \bumpeq(\lambda x . M) N$, and both given mcd-reductions contract the residual of $P$.
Then $P \triangleright_{\text {mad }} Q$ has the form

$$
P \bumpeq(\lambda x . M) N \triangleright_{\operatorname{mcd}}\left(\lambda x . M^{\prime}\right) N^{\prime} \triangleright_{1 \beta} M^{\prime}\left[N^{\prime} / x\right] \bumpeq Q
$$

and $P \triangleright_{\mathrm{mcd}} R$ has the form

$$
P \bumpeq(\lambda x . M) N \triangleright_{\text {med }}\left(\lambda x \cdot M^{\prime \prime}\right) N^{\prime \prime} \triangleright_{1 \beta} M^{\prime \prime}\left[N^{\prime \prime} / x\right] \bumpeq R
$$

We argue as in case 4 and choose $T: \bumpeq M^{+}\left[N^{+} / x\right]$. By Lemma 1.17 we obtain the result.

QED

Remark. The proof of confluence of $\triangleright_{\text {mcd }}$ depends crucially on the fact that all redexes are already present in the initial term, which enables us to control them.

Proof of Theorem 1.13 (1). Using confluence of $\triangleright_{\text {mad }}$ (Lemma 1.18) one can show that if $P \triangleright_{\text {mad }} M$ and $P \triangleright_{\beta} N$, then there exists a term $T$ such that $M \triangleright_{\beta} T$ and $N \triangleright_{\text {mad }} T$ by an induction according to the scheme:

Note that $P \triangleright_{1 \beta} Q$ implies $P \triangleright_{\text {med }} Q, P \triangleright_{\mathrm{mcd}} Q$ implies $P \triangleright_{\beta} Q$, and $\triangleright_{\beta}$ is transitive. Therefore:

If $P \triangleright_{1 \beta} M$ and $P \triangleright_{\beta} N$, then there exists a term $T$ such that $M \triangleright_{\beta} T$ and $N \triangleright_{\beta} T$.
From this the result follows by an induction according to the scheme:

That is, we obtain:

QED

## Corollary $\mathbf{1 . 1 9}$

1. If $M$ and $N$ are $\beta$-normal forms of $P$, then $M \equiv{ }_{\alpha} N$.
(That is, $\beta$-normal forms are unique modulo congruence.)
2. If $M={ }_{\beta} N$ and $N$ is in $\beta$-nf, then $M \triangleright_{\beta} N$.
(By the Church-Rosser Theorem, both $M$ and $N$ reduce to a term $T$. Since $N$ is in $\beta$-normal form, $N \equiv{ }_{\alpha} T$. Thus $M \triangleright_{\beta} N$.)
3. If $M={ }_{\beta} N$, then either both $M$ and $N$ have no $\beta$-nf, or both have the same $\beta$-nf (modulo congruence).
4. If $M={ }_{\beta} N$ and $M, N$ are in $\beta$-normal form, then $M \equiv{ }_{\alpha} N$.
(Thus $\lambda$-calculus is consistent in the sense that not all $\lambda$-terms are $\beta$-equal; in other words, the relation $={ }_{\beta}$ is not trivial. Consider the two terms $\lambda x y . x y$ and $\lambda x y . y x$. Both terms are in $\beta$-normal form, but they are not congruent. By the corollary, they are not $\beta$-equal.)

## Definition 1.20

- A leftmost reduction series (short: L-reduction series) is a $\beta$-reduction series, in which always the leftmost redex is contracted. A redex $\left(\lambda x_{1} \cdot M_{1}\right) N_{1}$ is to the left of $\left(\lambda x_{2} \cdot M_{2}\right) N_{2}$ (in the considered term), if $\lambda x_{1}$ stands to the left of $\lambda x_{2}$.
- A quasi-leftmost reduction series (short: QL-reduction series) is a $\beta$-reduction series $\left(M_{1}, M_{2}, M_{3}, \ldots\right)$ such that for each $M_{i}$ that is not the last element of the series there is an $M_{j}$ and an $M_{j+1}$ with $j \geq i$ such that in the contraction of $M_{j}$ to $M_{j+1}$ the leftmost redex in $M_{j}$ is contracted.

## Remarks.

1. A quasi-leftmost reduction series is a $\beta$-reduction series, in which every now and then the leftmost redex is contracted.
2. Leftmost reduction series correspond to lazy evaluation in programming languages.

Example. A leftmost reduction series for the term

$$
\overbrace{((\lambda x . x) \underbrace{((\lambda y . y y)(\lambda z . z))}_{\text {redex } 2})}^{\text {redex } 1}) \underbrace{((\lambda u . u)(\lambda v . v))}_{\text {redex } 3}
$$

is given by:

$$
\begin{aligned}
\underbrace{((\lambda x . x)((\lambda y . y y)(\lambda z . z)))}_{\text {leftmost redex }}((\lambda u . u)(\lambda v . v)) & \triangleright_{1 \beta} \\
& \underbrace{}_{1 \beta} \underbrace{((\lambda y . y y)(\lambda z . z))}_{\text {leftmost redex }}((\lambda u . u)(\lambda v . v)) \\
\underbrace{((\lambda z . z)(\lambda z . z))}_{1 \beta}((\lambda u . u)(\lambda v . v)) & \underbrace{(\lambda z . z)((\lambda u \cdot u)(\lambda v . v))}_{\text {leftmost redex }} \\
& \triangleright_{1 \beta} \underbrace{(\lambda u . u)(\lambda v . v)}_{\text {leftmost redex }} \\
& \triangleright_{1 \beta} \lambda v . v
\end{aligned}
$$

Theorem 1.21 If a $\lambda$-term $M$ has a $\beta$-normal form, then each leftmost reduction series beginning with $M$ terminates (and thus also each quasi-leftmost reduction series for $M$ ).

## Remarks.

1. For the proofs see Barendregt (2012), § 13.2.
2. The contraposition of this theorem is especially useful: In order to show that a term $M$ has no $\beta$-normal form, it is sufficient to show that there exists a non-terminating leftmost or quasi-leftmost reduction series beginning with $M$.

Theorem 1.22 There exist fixed-point combinators $Y$, i.e., combinators such that

1. $Y x={ }_{\beta} x(Y x)$,
or even
2. $Y x \triangleright_{\beta} x(Y x)$.

## Proof.

1. For the combinator

$$
\Upsilon: \bumpeq \lambda x \cdot(\lambda y \cdot x(y y)) \underbrace{(\lambda y \cdot x(y y))}_{\bumpeq: M}
$$

we have

$$
\Upsilon_{x} \triangleright_{\beta} M M \triangleright_{\beta} x(M M) \triangleleft_{\beta} x(\Upsilon x)
$$

However, (2) does not hold for $\Upsilon$. (This fixed-point combinator is due to Curry; cp. Rosenbloom, 1950.)
2. For the combinator

$$
\Theta: \bumpeq(\lambda z x \cdot x(z z x)) \underbrace{(\lambda z x \cdot x(z z x))}_{\bumpeq: N}
$$

we have

$$
\boldsymbol{\Theta} x \triangleright_{\beta}(\lambda x \cdot x(N N x)) x \triangleright_{\beta} x(N N x) \bumpeq x(\boldsymbol{\Theta} x)
$$

Thus (1) obviously holds for $\boldsymbol{\Theta}$, too. (This fixed-point combinator was given by Turing, 1937.)

QED

Corollary 1.23 For each $N$ there is an $M$ such that for $n \geq 0: M y_{1} \ldots y_{n}={ }_{\beta} N[M / x]$.
Proof. Let $M: \bumpeq Y\left(\lambda x y_{1} \ldots y_{n} \cdot N\right)$ for a fixed-point combinator $Y$. QED

## Remarks.

1. If for $Y$ we choose the fixed-point combinator $\boldsymbol{\Theta}$, i.e. $M: \bumpeq \boldsymbol{\Theta}\left(\lambda x y_{1} \ldots y_{n} . N\right)$, then even $M y_{1} \ldots y_{n} \triangleright_{\beta} N[M / x]$ holds.
2. Each "intuitive" equation of the form $x y_{1} \ldots y_{n}=N$ defining $x$ by a term $N$, where $x$ itself may occur in $N$ (i.e. the equation is "self-referential" in this sense) has some term $M$ as its solution.
3. A solution $M$ does not always represent a computable function. The corollary only tells us that there always is a solution $M$ in the "realm of $\lambda$-terms".

Theorem 1.24 $M$ is a fixed-point combinator, i.e. $M x={ }_{\beta} x(M x)$, iff $M$ is a fixed point of $\mathbf{S I}$, i.e. if $M={ }_{\beta} \mathbf{S I} M$.

Proof. (See Barendregt, 2012, Lemma 6.5.3.)
It is $\mathbf{S I}={ }_{\beta} \lambda y z . z(y z)$.
Let $M$ be a fixed point of SI, i.e. $M={ }_{\beta} \mathbf{S I} M$. Then $M N={ }_{\beta} \mathbf{S I} M N={ }_{\beta} N(M N)$, i.e. $M$ is a fixed-point combinator.
Let $M x={ }_{\beta} x(M x)$. Then $M x$ is not in in normal form, since otherwise $M x$ and $x(M x)$ would be congruent.
Thus $M x \triangleright_{\beta} x P$ and $x(M x) \triangleright_{\beta} x P$ for some term $P$. Moreover, $M \triangleright_{\beta} \lambda z . N$, since $M$ being a combinator it cannot begin with a variable. Therefore

$$
\lambda x \cdot M x={ }_{\beta} \lambda x \cdot(\lambda z \cdot N) x={ }_{\beta} \lambda x \cdot N[x / z]={ }_{\beta} M
$$

(That is, $\eta$-conversion, as defined below, is provable for $M$.)
Thus $M={ }_{\beta} \lambda x \cdot M x={ }_{\beta} \lambda x \cdot x(M x)={ }_{\beta} \mathbf{S I M} . \quad$ QED

## Definition 1.25

- A term of the form $\lambda x . M x$ is called $\eta$-redex, if $x \notin \operatorname{FV}(M)$. The term $M$ is its contractum.
- The operation of $\eta$-contraction is defined by:

$$
P[\lambda x . M x] \triangleright_{1 \eta} P[M], \text { if } x \notin \mathrm{FV}(M) .
$$

(The $\beta \eta$-equal terms are also called $\beta \eta$-convertible. If no $\beta$-contractions occur, then we speak of $\eta$-conversion $=\eta$.)
$\eta$-redex
contractum
$\eta$-contraction
$\beta \eta$-conversion $\eta$-conversion

Remark. Intuitively, $\beta \eta$-equality says that the meaning of a term depends only on its behaviour w.r.t. applications to another term (in other words, if extensionality obtains; cp. Lemma 1.38).

Lemma 1.26 Lemma 1.10 holds as well for $\triangleright_{\beta \eta}$.
Theorem 1.27 Church-Rosser holds for $\beta \eta$-reduction.
Proof. See Hindley \& Seldin (2008), appendix A2B.

### 1.2 The $\lambda$-definability of recursive functions

Definition 1.28 Let $M^{0} N: \bumpeq N$ and $M^{n+1} N: \bumpeq M\left(M^{n} N\right)$.
Then Church numerals are defined as follows: $\underline{n}: \bumpeq \lambda x y \cdot x^{n} y$.

## Remarks.

1. The notation $M^{n}$ is here used only in combinations $M^{n} N$, never alone.
2. Cp. Wittgenstein (1922), 6.021: "A number is the exponent of an operation".
3. If $\underline{m}={ }_{\beta} \underline{n}$, then $m=n$, since Church numerals are in $\beta$-normal form.
4. We have $\underline{n} P Q \triangleright_{\beta} P^{n} Q$.

Lemma 1.29 There exist combinators $\mathbf{N}, \mathbf{V}, \mathbf{D}$ and $\mathbf{R}$ with the following properties:

1. $\mathbf{N} \underline{k}={ }_{\beta} \underline{k+1} \quad$ (successor)
2. $\mathbf{V} \underline{k+1}={ }_{\beta} \underline{k} \quad$ (predecessor)
3. $\mathbf{D} P Q \underline{0}={ }_{\beta} P \quad$ (pairing- or conditional combinator; if-then-else)
$\mathbf{D} P Q \underline{k+1}={ }_{\beta} Q$
4. $\mathbf{R} P Q \underline{0}={ }_{\beta} P \quad$ (recursion combinator)
$\mathbf{R} P Q \underline{k}+1={ }_{\beta} Q \underline{k}(\mathbf{R} P Q \underline{k})$

## Remarks.

1. D $\underline{n} \underline{m}$ corresponds to the ordered pair $\langle n, m\rangle$, since according to (3) one can select the first or the second element.
2. $\mathbf{D} P Q \underline{n}$ corresponds to the operator if $n=0$ then $P$, else $Q$.

## Proof of Lemma 1.29.

1. $\mathbf{N}: \bumpeq \lambda u x y . x(u x y)$
2. $\mathbf{D}: \bumpeq \lambda x y z . z(\mathbf{K} y) x$
3. $\mathbf{V}: \bumpeq \lambda x \cdot x(\lambda z \cdot \mathbf{D}(\mathbf{N}(z \underline{0}))(z \underline{0}))(\mathbf{D} \underline{0} \underline{0}) \underline{1}$

We show by induction on $k$ :

$$
(\underbrace{\lambda z \cdot \mathbf{D}(\mathbf{N}(z \underline{0}))(z \underline{0})}_{\bumpeq:: P})^{k+1}(\mathbf{D} \underline{0} \underline{0})={ }_{\beta} \mathbf{D} \underline{k+1} \underline{k}
$$

Induction base:

$$
P^{1}(\mathbf{D} \underline{0} \underline{0})={ }_{\beta} \mathbf{D}(\mathbf{N}(\mathbf{D} \underline{0} \underline{0} \underline{0}))(\mathbf{D} \underline{0} \underline{0} \underline{0})={ }_{\beta} \mathbf{D}(\mathbf{N} \underline{0}) \underline{0}={ }_{\beta} \mathbf{D} \underline{1} \underline{0}
$$

Induction step: Let $P^{k+1}(\underline{\mathbf{D}} \underline{0})={ }_{\beta} \mathbf{D} \underline{k+1} \underline{k}$. Then

$$
\begin{aligned}
P^{k+2}(\underline{\mathbf{D}} \underline{0} \underline{0}) & ={ }_{\beta} P\left(P^{k+1}(\mathbf{D} \underline{0} \underline{0})\right) \\
& ={ }_{\beta} P(\mathbf{D} \underline{k+1} \underline{k}) \quad \text { (induction hypothesis) }
\end{aligned}
$$

$$
\begin{aligned}
& ={ }_{\beta} \mathbf{D}(\mathbf{N}(\mathbf{D} \underline{k+1} \underline{k} \underline{0}))(\mathbf{D} \underline{k+1} \underline{k} \underline{0}) \\
& ={ }_{\beta} \mathbf{D}(\mathbf{N} \underline{k+1}) \underline{k+1} \\
& ={ }_{\beta} \mathbf{D} \underline{k+2} \underline{k+1}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\mathbf{V} \underline{k+1} & ={ }_{\beta} \underline{k+1} P(\mathbf{D} \underline{0} \underline{0}) \underline{1} \\
& ={ }_{\beta} P^{k+1}(\mathbf{D} \underline{0} \underline{0}) \underline{1} \\
& ={ }_{\beta} \mathbf{D} \underline{k+1} \underline{k} \underline{1} \\
& ={ }_{\beta} \underline{k}
\end{aligned}
$$

4. $\mathbf{R}: \bumpeq \boldsymbol{\Theta}(\lambda u x y z . \mathbf{D} x(y(\mathbf{V} z)(u x y(\mathbf{V} z))) z)$

By Corollary 1.23, $\mathbf{R}$ is a solution of $\mathbf{R} x y z={ }_{\beta} \mathbf{D} x(y(\mathbf{V} z)(\mathbf{R} x y(\mathbf{V} z))) z . \quad$ QED

Remark. The recursion combinator $\mathbf{R}$ can also be given without using a fixed-point combinator. See Hindley \& Seldin (2008), proof of theorem 4.11, where the recursion combinator is given as a strongly normalising term.

Definition 1.30 A $\lambda$-term $P$ defines (or represents) a $k$-ary number-theoretic function $f$, if for all $m_{1}, \ldots, m_{k}$ the following holds: $P \underline{m_{1}} \ldots \underline{m_{k}} \simeq_{\beta} \underline{f\left(m_{1}, \ldots, m_{k}\right)}$. Using the abbreviation $\vec{m}$ for $m_{1}, \ldots, m_{k}$ the latter is also written $P \underline{\vec{m}} \simeq_{\beta} \underline{f(\vec{m})}$.

$$
P \underline{\vec{m}} \simeq_{\beta} \underline{n} \text { means that } \begin{cases}P \underline{\vec{m}}=_{\beta} \underline{n} \Longleftrightarrow f(\vec{m})=n, & \text { if } f(\vec{m}) \text { is defined } \\ P \underline{\vec{m}} \text { has no } \beta \text {-normal form, } & \text { if } f(\vec{m}) \text { is not defined. }\end{cases}
$$

Definition 1.31 The primitive recursive functions are defined inductively as follows:

1. The number $0: \mathbb{N}^{0} \rightarrow \mathbb{N}$ is a 0 -ary primitive recursive function.
primitive recursive function
2. The successor function $s: \mathbb{N} \rightarrow \mathbb{N}$ with $s(n)=n+1$ is primitive recursive.
3. For each $n \geq 1$ and $i \leq n$ the projection $\pi_{i}^{n}: \mathbb{N}^{n} \rightarrow \mathbb{N}$, where

$$
\pi_{i}^{n}\left(m_{1}, \ldots, m_{n}\right)=m_{i} \quad\left(m_{1}, \ldots, m_{n} \in \mathbb{N}\right)
$$

is primitive recursive.
4. If $n \geq 1$ and $1 \leq i \leq k$, and $h: \mathbb{N}^{k} \rightarrow \mathbb{N}$ and all $g_{i}: \mathbb{N}^{n} \rightarrow \mathbb{N}$ are primitive recursive, then so is the function $f: \mathbb{N}^{n} \rightarrow \mathbb{N}$, defined by composition as follows:

$$
f\left(m_{1}, \ldots, m_{n}\right)=h\left(g_{1}\left(m_{1}, \ldots, m_{n}\right), \ldots, g_{k}\left(m_{1}, \ldots, m_{n}\right)\right)
$$

5. If $k \geq 0$, and $g: \mathbb{N}^{k} \rightarrow \mathbb{N}$ and $h: \mathbb{N}^{k+2} \rightarrow \mathbb{N}$ are primitive recursive, then so is the
function $f: \mathbb{N}^{k+1} \rightarrow \mathbb{N}$, defined by recursion as follows:

$$
\begin{aligned}
f\left(0, m_{1}, \ldots, m_{k}\right) & =g\left(m_{1}, \ldots, m_{k}\right) \\
f\left(n+1, m_{1}, \ldots, m_{k}\right) & =h\left(n, f\left(n, m_{1}, \ldots, m_{k}\right), m_{1}, \ldots, m_{k}\right)
\end{aligned}
$$

Remark. Instead of $h\left(g_{1}(\vec{m}), \ldots, g_{k}(\vec{m})\right)$ we also write $\left(h \circ\left[g_{1} ; \ldots ; g_{k}\right]\right)(\vec{m})$.
Theorem 1.32 Every primitive recursive function is $\lambda$-definable.
Proof. We present $\lambda$-terms that correspond to clauses (1)-(5) in Definition 1.31.

1. $0: \mathbb{N}^{0} \rightarrow \mathbb{N}$ is $\lambda$-defined by the term $\underline{0}$.
2. $s: \mathbb{N} \rightarrow \mathbb{N}$ is $\lambda$-defined by the term $\mathbf{N}$.
3. $\pi_{i}^{n}: \mathbb{N}^{n} \rightarrow \mathbb{N}$ is $\lambda$-defined by the term $\lambda x_{1} \ldots x_{n} . x_{i}$.
4. If $h: \mathbb{N}^{k} \rightarrow \mathbb{N}$ and $g_{i}: \mathbb{N}^{n} \rightarrow \mathbb{N}$ are $\lambda$-defined by $P$ and $Q_{i}$, respectively, $(1 \leq i \leq k)$, and $f: \mathbb{N}^{n} \rightarrow \mathbb{N}$ is given by $f(\vec{m}):=\left(h \circ\left[g_{1} ; \ldots ; g_{k}\right]\right)(\vec{m})$ for all $\vec{m}=\left(m_{1}, \ldots, m_{n}\right)$, then the function $f: \mathbb{N}^{n} \rightarrow \mathbb{N}$ is $\lambda$-defined by the term $\lambda \vec{x} \cdot P\left(Q_{1} \vec{x}\right) \ldots\left(Q_{k} \vec{x}\right)$, where $Q_{i} \vec{x}: \bumpeq\left(\ldots\left(Q_{i} x_{1}\right) \ldots\right) x_{n}$.
5. If $g: \mathbb{N}^{k} \rightarrow \mathbb{N}$ and $h: \mathbb{N}^{k+2} \rightarrow \mathbb{N}$ are $\lambda$-defined by $\lambda$-terms $P$ and $Q$, and $f: \mathbb{N}^{k+1} \rightarrow \mathbb{N}$ is given by

$$
\begin{aligned}
f(0, \vec{m}) & =g(\vec{m}) \\
f(n+1, \vec{m}) & =h(n, f(n, \vec{m}), \vec{m})
\end{aligned}
$$

then $f$ is $\lambda$-defined by the term $\lambda u \vec{x} \cdot \mathbf{R}(P \vec{x})(\lambda u v \cdot Q u v \vec{x}) u$.
Proof by induction on $n$ :
Induction base:

$$
\begin{aligned}
(\lambda u \vec{x} \cdot \mathbf{R}(P \vec{x})(\lambda u v \cdot Q u v \vec{x}) u) \underline{0} \underline{\vec{m}} & ={ }_{\beta} \mathbf{R}(P \underline{\vec{m}})(\lambda u v \cdot Q u v \underline{\vec{m}}) \underline{0} \\
& ={ }_{\beta} P \underline{\vec{m}} \\
& \left.={ }_{\beta} \underline{g(\vec{m})} \quad \text { (by presupposition on } g\right)
\end{aligned}
$$

Induction step:

$$
\begin{aligned}
(\lambda u \vec{x} \cdot \mathbf{R}(P \vec{x})(\lambda u v \cdot Q u v \vec{x}) u) \underline{n+1} \underline{\vec{m}} & ={ }_{\beta} \mathbf{R}(P \underline{\vec{m}})(\lambda u v \cdot Q u v \underline{\vec{m}}) \underline{n+1} \\
& ={ }_{\beta}(\lambda u v \cdot Q u v \underline{\vec{m}}) \underline{n}(\mathbf{R}(P \underline{\vec{m}})(\lambda u v \cdot Q u v \underline{\vec{m}}) \underline{n}) \\
& ={ }_{\beta} Q \underline{n}(\mathbf{R}(P \underline{\vec{m}})(\lambda u v \cdot Q u v \underline{\vec{m}}) \underline{n}) \underline{\vec{m}} \\
& ={ }_{\beta} Q \underline{n}((\lambda u \vec{x} \cdot \mathbf{R}(P \vec{x})(\lambda u v \cdot Q u v \vec{x}) u) \underline{n} \underline{\vec{m}}) \underline{\vec{m}} \\
& ={ }_{\beta} Q \underline{n} \underline{f(n, \vec{m})} \underline{\vec{m}} \quad(\text { induction hypothesis) } \\
& ={ }_{\beta} \underline{h(n, f(n, \vec{m}), \vec{m}) \quad \text { (by presupp. on } h)}
\end{aligned}
$$

Example. The function $a d d: \mathbb{N}^{2} \rightarrow \mathbb{N}$ with $\operatorname{add}(n, m)=n+m$ is defined primitive recursively as follows:

$$
\begin{aligned}
\operatorname{add}(0, m) & =\pi_{1}^{1}(m) \\
\operatorname{add}(n+1, m) & =\left(s \circ \pi_{2}^{3}\right)(n, \operatorname{add}(n, m), m)
\end{aligned}
$$

The $\lambda$-definition of the function $\pi_{1}^{1}$ is the term $\lambda x . x \bumpeq \mathbf{I}$, and the $\lambda$-definition of composition $s \circ \pi_{2}^{3}$ is the term $\lambda y_{1} y_{2} y_{3} \cdot \mathbf{N}\left(\left(\lambda x_{1} x_{2} x_{3} \cdot x_{2}\right) y_{1} y_{2} y_{3}\right)$.
By schema (5) the $\lambda$-definition of $a d d$ is thus the term

$$
\mathbf{A d d} \bumpeq \lambda u x . \mathbf{R}(\mathbf{I} x)\left(\lambda u v .\left(\lambda y_{1} y_{2} y_{3} . \mathbf{N}\left(\left(\lambda x_{1} x_{2} x_{3} \cdot x_{2}\right) y_{1} y_{2} y_{3}\right)\right) u v x\right) u
$$

All redexes generated by this schematic translation can be contracted, yielding the following simplified term:

$$
\text { Add } \triangleright_{\beta} \lambda u x . \mathbf{R} x(\lambda u v . \mathbf{N} v) u
$$

The computation of $1+1$ (using Lemma 1.29, 4 and 1 ) is as follows:

$$
\begin{aligned}
\operatorname{Add} \underline{1} \underline{1} & \triangleright_{\beta} \mathbf{R} \underline{1}(\lambda u v \cdot \mathbf{N} v) \underline{1} \\
& ={ }_{\beta}(\lambda u v \cdot \mathbf{N} v) \underline{0}(\mathbf{R} \underline{1}(\lambda u v \cdot \mathbf{N} v) \underline{0}) \\
& \triangleright_{\beta} \mathbf{N}(\mathbf{R} \underline{1}(\lambda u v \cdot \mathbf{N} v) \underline{0}) \\
& ={ }_{\beta} \mathbf{N} \underline{1} \\
& ={ }_{\beta} \underline{2}
\end{aligned}
$$

Definition 1.33 A function $f: \mathbb{N}^{n} \rightarrow \mathbb{N}$ (for $n \geq 0$ ) is called partial recursive iff there exist primitive recursive functions $g$ and $h$, such that for all $\vec{m}=\left(m_{1}, \ldots, m_{n}\right)$
partial recursive function

$$
f(\vec{m})=h(\mu k \cdot g(\vec{m}, k)=0)
$$

where the $\mu$-operator is defined as follows:

$$
(\mu k . g(\vec{m}, k)=0):=\left\{\begin{array}{l}
\text { the smallest } k, \text { such that } g(\vec{m}, k)=0 \text { holds, } \\
\text { if there exists such a } k \\
\text { undefined, if no such } k \text { exists. }
\end{array}\right.
$$

If a smallest $k$ always exists, then the function $f(\vec{m})=h(\mu k \cdot g(\vec{m}, k)=0)$ is called recursive or total recursive.
total recursive function

Theorem 1.34 Every partial recursive function is $\lambda$-definable.

Proof. We consider partial recursive functions

$$
f(\vec{m}):=h(\mu k \cdot g(\vec{m}, k)=0),
$$

where $g$ and $h$ shall be primitive recursive functions, $\lambda$-defined by terms $P$ and $Q$, respectively (cp. Theorem 1.31).

Approach: To compute $\mu k . g(\vec{m}, k)=0$ one can write a program $F$ such that $F(k)$ outputs $k$ if $g(\vec{m}, k)=0$, and otherwise calls $F(k+1)$. If we run this program for $k=0$ we obtain the smallest $k$ such that $g(\vec{m}, k)=0$.

We thus have to find a corresponding term $M$ such that (in crude terms) the following holds:

$$
M \vec{x} y=(\text { if } P \vec{x} y=0, \text { then } y, \text { else } M \vec{x} y+1)
$$

The function $f(\vec{m})$ could then be represented by the term $\lambda \vec{x} \cdot Q(M \vec{x} \underline{0})$.
Consider the equation

$$
M \vec{x} y={ }_{\beta} \mathbf{D} y(M \vec{x}(\mathbf{N} y))(P \vec{x} y)
$$

By Corollary 1.23, $\boldsymbol{\Theta} \underbrace{(\lambda u \vec{x} y \cdot \mathbf{D} y(u \vec{x}(\mathbf{N} y))(P \vec{x} y))}_{\approx: Z}$ is a solution of this equation
Claim: $f$ is $\lambda$-defined by the term $\lambda \vec{x} \cdot Q(\boldsymbol{\Theta} Z \vec{x} \underline{0})$.
It is sufficient to show

$$
\Theta Z \underline{\vec{m}} \underline{0}={ }_{\beta} \underline{k_{1}} \text {, if } k_{1} \text { is the smallest } k \text { with } g(\vec{m}, k)=0
$$

(since then $Q \underline{k_{1}}=\beta \underline{f(\vec{m})}$ ).
We will show:

$$
\text { If } g(\vec{m}, k) \neq 0 \text { for all } k<k_{1} \text {, then } \Theta Z \underline{\vec{m}} \underline{0}={ }_{\beta} \mathbf{D} \underline{k_{1}}\left(\Theta Z \underline{\vec{m}} \underline{k_{1}+1}\right)\left(P \underline{\vec{m}} \underline{k_{1}}\right) .
$$

This entails:

If $k_{1}$ is the smallest $k$ with $g(\vec{m}, k)=0$, then $\Theta Z \underline{\vec{m}} \underline{0}={ }_{\beta} \underline{k_{1}}$, since $P \underline{\vec{m}} \underline{k_{1}}={ }_{\beta} \underline{0}$.
Proof of ( $(\star \star)$ by induction on $k_{1}$ :
For $k_{1}=0: ~ \boldsymbol{\Theta} Z \underline{\vec{m}} \underline{0}={ }_{\beta} \mathbf{D} \underline{0}(\boldsymbol{\Theta} Z \underline{\vec{m}} \underline{1})(P \underline{\vec{m}} \underline{0}) \quad$ by $(\star)$
For $k_{1}>0$ :

$$
\begin{aligned}
& \Theta Z \underline{\vec{m}} \underline{0}={ }_{\beta} \mathbf{D} \underline{k_{1}-1}\left(\Theta Z \underline{\vec{m}} \underline{k_{1}}\right) \underbrace{\left(P \underline{\vec{m}} \underline{\left.k_{1}-1\right)}\right.} \quad \text { (induction hypothesis) } \\
&={ }_{\beta} \underline{l+1} \text { for an } l \geq 0, \text { since } g\left(\vec{m}, k_{1}-1\right) \neq 0 ; \\
& \text { thus } P \underline{\underline{m}} \underline{k_{1}-1} \neq{ }_{\beta} \underline{0}
\end{aligned}
$$

$$
\begin{aligned}
& ={ }_{\beta} \Theta Z \underline{\vec{m}} \underline{k_{1}} \\
& ={ }_{\beta} \mathbf{D} \underline{k_{1}}\left(\Theta Z \underline{\vec{m}} \underline{k_{1}+1}\right)\left(P \underline{\vec{m}} \underline{k_{1}}\right) \quad \text { by }(\star)
\end{aligned}
$$

It remains to show:
If $f(\vec{m})$ is undefined, i.e., if $g(\vec{m}, k) \neq 0$ for all $k$ and given $\vec{m}$, then $\Theta Z \underline{\vec{m}} \underline{0}$ has no $\beta$-normal form.

By ( $\star$ ) we have:

$$
\boldsymbol{\Theta} Z \underline{\vec{m}} \underline{k_{1}}={ }_{\beta} \mathbf{D} \underline{k_{1}}\left(\boldsymbol{\Theta} Z \underline{\vec{m}} \underline{k_{1}+1}\right)\left(P \underline{\vec{m}} \underline{k_{1}}\right)
$$

and since we have chosen $\Theta$ (and not $\Upsilon$ ) as fixed-point combinator we even have (cp. the remark after Corollary 1.23):

$$
\Theta Z \underline{\vec{m}} \underline{k_{1}} \triangleright_{\beta} \mathbf{D} \underline{k_{1}}\left(\Theta Z \underline{\vec{m}} \underline{k_{1}+1}\right)\left(P \underline{\vec{m}} \underline{k_{1}}\right)
$$

By supposition $P \underline{\vec{~}} \underline{k} \neq \beta \underline{0}$ for every $\underline{k}$. Therefore:

$$
\begin{aligned}
\Theta & Z \underline{\vec{m}} \underline{0} \triangleright_{\beta} \mathbf{D} \underline{0}(\Theta Z \underline{\vec{m}} \underline{1})(P \underline{\vec{m}} \underline{0}) \triangleright_{\beta} \Theta Z \underline{\vec{m}} \underline{1} \\
& \triangleright_{\beta} \mathbf{D} \underline{1}(\Theta Z \underline{\vec{m}} \underline{2})(P \underline{\vec{m}} \underline{1}) \triangleright_{\beta} \Theta Z \underline{\vec{m}} \underline{2} \\
& \triangleright_{\beta} \mathbf{D} \underline{2}(\Theta Z \underline{\vec{m}} \underline{3})(P \underline{\vec{m}} \underline{2}) \triangleright_{\beta} \Theta Z \underline{\vec{m}} \underline{3} \\
& \triangleright_{\beta} \cdots
\end{aligned}
$$

This $\beta$-reduction series is quasi-leftmost. That is, from time to time a leftmost term is contracted, namely a term of the form $\mathbf{D} M N \underline{l+1}$. Moreover, the reduction series is not terminating. The term $\Theta Z \underline{\vec{~}} \underline{0}$ has therefore no $\beta$-normal form (cp. Theorem 1.20). QED

Theorem 1.35 Every $\lambda$-definable function is partial recursive.
Sketch of proof. Let $f$ be an $n$-ary function which is $\lambda$-defined by a term $P$. Then
$f\left(k_{1}, \ldots, k_{n}\right)=$ that $k$ for which the equation $P \underline{k_{1}} \ldots \underline{k_{n}}=\underline{k}$ is endformula of the shortest derivation in $\lambda \beta$ (see Section $\overline{1.3}$ ) ending with a formula of the form $P \underline{k_{1}} \ldots \underline{k_{n}}=\underline{m}$, if there exists such a derivation in $\lambda \beta$.

Otherwise $f\left(k_{1}, \ldots, k_{n}\right)$ is undefined.
Using Gödelisation (cp. the remark on p. 33) $f$ can be seen to be a partial recursive function.

QED

### 1.3 The formal theories $\lambda \boldsymbol{\beta}$ and $\lambda \boldsymbol{\beta} \eta$

Our treatment of the $\lambda$-calculus has so far been based on the operational semantics for $\lambda$-terms given by $\beta$-contraction, $\alpha$-conversion and possibly $\eta$-contraction. We now consider formal systems that are sound and complete with respect to this semantics.

Definition 1.36 We define the formal theories $\lambda \beta$ and $\lambda \beta \eta$, whose formulas are all equations of the form $M=N$ for $\lambda$-terms $M, N$.
( $\alpha$ ) $\lambda x \cdot M=\lambda y \cdot M[y / x]$, if $y \notin \mathrm{FV}(M)$
( $\beta$ ) $(\lambda x \cdot M) N=M[N / x]$
( $\rho$ ) $M=M \quad$ (reflexivity)
$\lambda \beta \eta$ has in addition:
( $\eta$ ) $\lambda x . M x=M$, if $x \notin \mathrm{FV}(M)$
The rules are:
( $\sigma$ ) $\frac{M=N}{N=M} \quad$ (symmetry)
( $\tau) \frac{M=N \quad N=P}{M=P} \quad$ (transitivity)
( $\mu$ ) $\frac{N}{}=N^{\prime} M^{\prime}$
(v) $\frac{M}{}=M^{\prime} ~\left(M N=M^{\prime} N\right.$
( $\xi$ ) $\frac{M}{}=M^{\prime} \quad$ (weak extensionality)
(Formulas above the rule bar are called premisses, the formula below is called conclusion.)
Let $\Gamma$ be a set of formulas and $A$ a formula. A derivation of $A$ from $\Gamma$ in $\lambda \beta$ or $\lambda \beta \eta$ is a tree (branching upward),

- whose leaves are axioms of $\lambda \beta$, resp. $\lambda \beta \eta$, or formulas in $\Gamma$,
- whose other (non-leaf) nodes are formulas inferred by a rule application from the immediately preceding formulas (i.e., formulas standing directly above),
- and whose root node is $A$.

The elements of $\Gamma$ are also called assumptions, and the formula $A$ is also called endformula. If $\mathcal{T}$ is a formal theory, then

$$
\mathcal{T}, \Gamma \vdash A
$$

means that $A$ is derivable in $\mathcal{T}$ from assumptions $\Gamma$. If $\Gamma=\emptyset$, then the derivation of $A$ in $\mathcal{T}$ is also called proof (of $A$ in $\mathcal{T}$ ), i.e.

$$
\begin{aligned}
& \lambda \beta \vdash M=N \text { means that } M=N \text { is provable in } \lambda \beta . \\
& \lambda \beta \eta \vdash M=N \text { means that } M=N \text { is provable in } \lambda \beta \eta \text {. }
\end{aligned}
$$

The two formal theories $\lambda \beta_{\triangleright}$ and $\lambda \beta \eta_{\triangleright}$ are defined like the systems $\lambda \beta$ and $\lambda \beta \eta$, respectively, but without rule $(\sigma)$, i.e. without symmetry.

$\qquad$
(aser
 proof
formal theories $\lambda \beta_{\triangleright}$ and $\lambda \beta \eta_{\triangleright}$

Then

$$
\begin{aligned}
& \lambda \beta_{\triangleright} \vdash M=N \text { means that } M=N \text { is provable in } \lambda \beta_{\triangleright} ; \\
& \lambda \beta \eta_{\triangleright} \vdash M=N \text { means that } M=N \text { is provable in } \lambda \beta \eta_{\triangleright} \text {. }
\end{aligned}
$$

Example. The derivation

$$
\begin{aligned}
& \quad(\beta) \overline{(\lambda y \cdot y x) z=z x} \\
& (\tau) \frac{(\xi) \frac{(\lambda x \cdot(\lambda y \cdot y x) z=\lambda x \cdot z x}{\lambda x \cdot y x) z) v=(\lambda x \cdot z x) v} \quad(\beta) \overline{(\lambda x \cdot z x) v=z v}}{(\lambda x \cdot(\lambda y \cdot y x) z) v=z v}
\end{aligned}
$$

is a proof of $(\lambda x .(\lambda y \cdot y x) z) v=z v$ in any of the above systems.

## Lemma 1.37

1. $M \triangleright_{\beta} N \Longleftrightarrow \lambda \beta_{\triangleright} \vdash M=N$
2. $M \triangleright_{\beta \eta} N \Longleftrightarrow \lambda \beta \eta_{\triangleright} \vdash M=N$
3. $M={ }_{\beta} N \Longleftrightarrow \lambda \beta \vdash M=N$
4. $M={ }_{\beta \eta} N \Longleftrightarrow \lambda \beta \eta \vdash M=N$

Proof. Exercise.
Remark. The relations on the left side are based on the operational semantics for $\lambda$-terms. The provability relations on the right side are based on the respective formal theories. The lemma thus says that the formal theories are sound (" $\Longleftarrow ")$ and complete (" $\Longrightarrow$ ") for the respective corresponding operational semantics.

Lemma 1.38 If, in the definition of $\lambda \beta \eta$, we replace axiom $(\eta)$ by the rule

$$
(\chi) \frac{M P=N P \text { for all } P}{M=N}
$$

or by the rule

$$
\text { (弓) } \frac{M x=N x}{M=N} \text { if } x \notin \mathrm{FV}(N M)
$$

then in the resulting systems the same equations are derivable as before.
Remark. Rule $(\chi)$ is a so-called $\omega$-rule, i.e. a rule having infinitely many premisses. We only consider rule ( $\zeta$ ) here. Both rules, as well as the axiom schema $(\eta)$, express extensionality of $=$.
For the equality of functions $f$ and $g$ extensionality means:

$$
\text { For all } x \text { : If } f(x)=g(x) \text {, then } f=g \text {. }
$$

One would not require extensionality for the equality of programs; one would rather
understand equality intensionally in this case. The theory $\lambda \beta$ (resp. $\lambda \beta_{\triangleright}$ ) is intensional as well, i.e. we do not have:

$$
\text { For all terms } X \text { : If } \lambda \beta \vdash M X=N X \text {, then } \lambda \beta \vdash M=N .
$$

(A counterexample can be obtained using the terms $M \bumpeq y$ and $N \bumpeq \lambda x . y x$.)
On the other hand, systems having $(\eta),(\chi)$ or $(\zeta)$ are extensional.
Proof of Lemma 1.38.
$"(\eta) \Longrightarrow(\zeta) ":$

$$
\begin{aligned}
& (\eta) \frac{\overline{\lambda x \cdot M x=M}}{(\sigma)} \begin{array}{l}
\frac{1}{M=\lambda x \cdot M x} \\
(\tau) \frac{M x=N x}{\lambda x \cdot M x=\lambda x \cdot N x} \\
(\tau) \frac{M=\lambda x \cdot N x}{M=N}
\end{array} \quad \text { ( } \frac{1)}{\lambda x \cdot N x=N} \\
&
\end{aligned}
$$

Thus applications of $(\zeta)$ can always be replaced by a derivation of this form.
$"(\zeta) \Longrightarrow(\eta) ":$

$$
\begin{aligned}
& (\beta) \overline{(\lambda x \cdot M x) x=M x} \\
& (\zeta)
\end{aligned}
$$

Thus any application of the axiom $(\eta)$ can be replaced by a derivation of this form. QED

### 1.4 Undecidability results

## Theorem 1.39 (Church, 1936b)

The set $N F_{\beta}:=\{M \mid M$ has $\beta$-normal form $\}$ is not decidable.
Sketch of proof. Consider an enumeration of the unary partial recursive functions $f_{1}, f_{2}, \ldots$ such that the function $u$ with $u(m, n): \simeq f_{m}(n)$ is partial recursive (such an enumeration exists).
Let $u$ be $\lambda$-defined by the term $P$. Then the following holds:

$$
P \underline{m} \underline{n} \text { has } \beta \text {-normal form } \Longleftrightarrow u(m, n) \text { is defined. }
$$

Suppose $N F_{\beta}$ were decidable. Then the following function $g$ would be a total recursive function:

$$
g(n):= \begin{cases}u(n, n)+1 & \text { if } u(n, n) \text { is defined } \\ 1 & \text { otherwise }\end{cases}
$$

Then $g=f_{k}$ for some $k$. Since $f_{k}$ is total, we have

$$
u(k, k)=f_{k}(k)=g(k)=u(k, k)+1
$$

Contradiction. QED

Remark. In what follows we presuppose that $\lambda$-terms can be encoded as natural numbers in such a way that different terms are always encoded by different numbers. Such an encoding is called Gödelisation. The number encoding a term $M$ is called Gödel number of $M$, written $\ulcorner M$. Then the $\lambda$-term $\ulcorner\underline{M}$ is the church numeral that corresponds to the Gödel number ${ }^{\ulcorner } M\ulcorner$ of $M$.

Theorem 1.40 (Church, 1936b) The relation $=_{\beta}$ is not decidable.
Sketch of proof. We can recursively enumerate all terms that are $\beta$-equal to a given term. For example, we can produce derivations of the corresponding equations in $\lambda \beta$, and use Lemma 1.37 (3).
Let

$$
\begin{aligned}
f(m, k):= & \text { Gödel number of the } k \text {-th term that is } \beta \text {-equal to the term with Gödel } \\
& \text { number } m ;
\end{aligned}
$$

$h(m):= \begin{cases}0 & \text { if } m \text { is the Gödel number of a term in } \beta \text {-normal form, } \\ 1 & \text { otherwise. }\end{cases}$
The functions $f$ and $h$ are primitive recursive. We assume they are $\lambda$-defined by the terms $F$ and $H$, respectively.
Consider the equation

$$
M x y={ }_{\beta} \mathbf{D} \underline{1}(M x(\mathbf{N} y))(H(F x y))
$$

By Corollary 1.23, the following is a solution of this equation:

$$
\boldsymbol{\Upsilon}(\lambda u x y \cdot \underbrace{\mathbf{D} \underline{1}(u x(\mathbf{N} y))(H(F x y))}_{\bumpeq: V})
$$

Then the following holds:
$-(\Upsilon(\lambda u x y . V)) \underline{m} \underline{0}=\beta \underline{1}$, if $m$ is the Gödel number of a term that is $\beta$-equal to a term in $\beta$-normal form.

- Otherwise $(\boldsymbol{\Upsilon}(\lambda u x y . V)) \underline{m} \underline{0}$ has no $\beta$-normal form.

Suppose $={ }_{\beta}$ were decidable. Then $(\boldsymbol{\Upsilon}(\lambda u x y . V)) \underline{M} \underline{0}={ }_{\beta} \underline{1}$ would be decidable. Thus $N F_{\beta}$ would be decidable, contradicting Theorem 1.39.

Theorem 1.41 (Church, 1936a) First-order logic PL is not decidable.
Sketch of proof. The relation $=_{\beta}$ is not decidable.
Thus, by Lemma 1.37 (3), the formal theory $\lambda \beta$ is not decidable either.
$\lambda \beta$ can be translated into a $P L$-formula:

- we use Gödel numbers to encode $\lambda$-terms;
- (Gödel) numbers can be represented by PL-terms $x, f(x), f(f(x)), \ldots$ in an obvious way (interpret the term $f$ as the successor function); we abbreviate these terms as follows:

$$
\begin{aligned}
& \overline{\overline{0}}: \bumpeq x \\
& \overline{\overline{1}}: \bumpeq f(x) \\
& \overline{\overline{2}}: \bumpeq f(f(x))
\end{aligned}
$$

- we use the binary relation symbol $E$ to represent equality $(=)$ in $\lambda \beta$;
- using $E$ we translate the 8 axiom schemata and rules of $\lambda \beta$ into $8 P L$-formulas $F_{1}$ to $F_{8}$ as follows:

1. Rule ( $\sigma$ )

$$
\frac{M=N}{N=M}
$$

is translated into the $P L$-formula

$$
E\left(\overline{\overline{\Gamma^{7}}}, \overline{\overline{\Gamma^{\top}}}\right) \rightarrow E\left(\overline{\overline{{ }^{\prime}} N^{7}}, \overline{\overline{\Gamma^{7}}}\right)
$$

2. Rule ( $\tau$ )

$$
\frac{M=N \quad N=P}{M=P}
$$

is translated into the $P L$-formula

$$
E\left(\overline{\overline{{ }^{M}}}, \overline{\overline{\ulcorner } N^{\urcorner}}\right) \wedge E\left(\overline{\overline{{ }^{\prime} N},} \overline{\overline{\ulcorner } P} \overline{\bar{\imath}}\right) \rightarrow E\left(\overline{\overline{{ }^{M}}}, \overline{\overline{\ulcorner } P^{\urcorner}}\right)
$$

And so on for the remaining rules and axiom schemata (variable conditions may be assumed and do not have to be translated).

Then the following holds:

$$
\lambda \beta \vdash M=N \Longleftrightarrow P L \vdash\left(F_{1} \wedge \ldots \wedge F_{8}\right) \rightarrow E\left(\overline{\overline{{ }^{M}}} \overline{\overline{\ulcorner }}, \overline{\overline{N^{\top}}}\right)
$$

Suppose $P L$ were decidable. Then $\lambda \beta$ would be decidable as well, and by Lemma 1.37 (3) also $\beta$-equality $\left(=_{\beta}\right)$, contradicting Theorem 1.40.

QED

## 2 Combinatory Logic

Combinatory logic (short: CL) is as powerful as $\lambda$-calculus, but without making use of bound variables. This simplifies substitution, and we do not need $\alpha$-conversion. However, CL-terms are less transparent than $\lambda$-terms.
To motivate the abandonment of bound variables we consider the law of commutativity for addition:

$$
\text { for all } x, y: x+y=y+x
$$

where the variables $x$ and $y$ occur bound. To avoid this binding of variables we first introduce an addition operator $A$ :

$$
A(x, y)=x+y \quad(\text { for all } x, y)
$$

and then define an operator $\mathbf{C}$ by

$$
(\mathbf{C}(f))(x, y)=f(y, x) \quad(\text { for all } f, x, y)
$$

The law of commutativity can then be given as follows:

$$
A=\mathbf{C}(A)
$$

In this formulation no bound variables occur (at least not immediately). The operator $\mathbf{C}$ is an example of a combinator. Further examples are:

| $\mathbf{B}$ | $(\mathbf{B}(f, g))(x)=f(g(x))$ | composition of two functions |
| :--- | :--- | :--- |
| $\mathbf{B}^{\prime}$ | $\left(\mathbf{B}^{\prime}(f, g)\right)(x)=g(f(x))$ | reverse composition of two functions |
| $\mathbf{S}$ | $(\mathbf{S}(f, g))(x)=f(x, g(x))$ | (stronger) composition of two functions |
| $\mathbf{I}$ | $\mathbf{I}(f)=f$ | identity |
| $\mathbf{K}$ | $(\mathbf{K}(c))(x)=c$ | forms constant functions |

### 2.1 Syntax and operational semantics

Let an infinite series of variables be given (in a fixed order). We assume that these variables are the same as in $\lambda$-calculus.
$\mathbf{K}$ and $\mathbf{S}$ shall be given as constants. If a system contains additional constants, then it is called applied, otherwise pure. We only investigate pure combinatory logic.

Definition 2.1 CL-terms are defined as follows:

1. All variables and constants (i.e. atoms) are CL-terms.
2. If $X$ and $Y$ are CL-terms, then the application $(X Y)$ is a CL-term as well, having $X$

CL-terms
atoms
application and $Y$ as immediate subterms.

## Further notions:

- A closed CL-term has no variables.
- A combinator has only $\mathbf{K}$ and $\mathbf{S}$ as atoms.
closed
combinator
- Metalinguistic variables (also with indexes):
- for CL-terms: $U, V, W, X, Y, Z, \ldots$
- for atoms: $a, b, c, \ldots$
$-\operatorname{FV}(X)$ denotes the set of variables in $X$.
- On parentheses:
- Outermost parentheses can be omitted.
- We use association to the left, i.e. $U V W X$ stands for $((U V) W) X$.
- $X \bumpeq Y$ denotes again the syntactic identity of $X$ and $Y$.
- The length of a term and the notion of (proper) subterm are defined as for $\lambda$-terms.

## Examples.

$-\mathbf{S} x y(\mathbf{K} y)(\mathbf{K K S S})$ is a CL-term.
$-\mathbf{S}(\mathbf{K S})$ is a CL-term (and a combinator).
Definition 2.2 As no bound variables can occur in CL-terms, substitution $Y[U / x]$ is substitution simply defined as follows:

1. $x[U / x]: \bumpeq U$,
2. $a[U / x]: \bumpeq a$, if $x \neq a$,
3. $(V W)[U / x]: \bumpeq(V[U / x] W[U / x])$.

## Definition 2.3

- A term of form $\mathbf{K} X Y$ or $\mathbf{S} X Y Z$ is called weak redex (short: redex).
- The operation of weak contraction is defined by:

$$
\begin{gathered}
U[\mathbf{K} X Y] \triangleright_{1 w} U[X] \\
U[\mathbf{S} X Y Z] \triangleright_{1 w} U[X Z(Y Z)]
\end{gathered}
$$

- If there is a (possibly empty) finite series of weak contractions from a term $X$ to a term $Y$, i.e. if

$$
X \bumpeq V_{1} \triangleright_{1 w} V_{2} \triangleright_{1 w} \cdots \triangleright_{1 w} V_{n} \bumpeq Y
$$

then $X$ (weakly) reduces to $Y$. Notation: $X \triangleright_{w} Y$.

- Two terms $X$ and $Y$ are weakly equal (or weakly convertible), if

$$
X \bumpeq V_{1} \stackrel{\triangleright_{1 w}}{\triangleleft_{1 w}} V_{2} \underset{1 w}{\triangleright_{1 w}} \ldots \underset{1 w}{\triangleright_{1 w}} V_{1 w} \bumpeq Y
$$

(where $U \underset{\triangleleft_{1 w} w}{\triangleright_{1 w}} W$ means " $U \triangleright_{1 w} W$ or $W \triangleright_{1 w} U$ "). Notation: $X={ }_{w} Y$.

- For a (possibly empty) finite or infinite series of weak contractions

$$
X \bumpeq X_{1} \triangleright_{1 w} X_{2} \triangleright_{1 w} X_{3} \triangleright_{1 w} \cdots
$$

we call $\left(X_{1}, X_{2}, X_{3}, \ldots\right)$, or the given series itself, a weak reduction series for $X$.
weak reduction series

## Definition 2.4

- $X$ is in weak normal form (short: weak $n f$ ), if $X$ contains no weak redex.
weak normal form
- If $X \triangleright_{w} Y$ holds, and $Y$ is in weak normal form, then $Y$ is a weak normal form of $X$. (We also say that $X$ has the weak normal form $Y$.)
- $X$ is (weakly) normalisable, if there is a weak normal form of $X$.
- $X$ is strongly normalisable, if there is no infinite weak reduction series for $X$.

## Examples.

normalisable
strongly
normalisable

1. Let $\mathbf{B}: \bumpeq \mathbf{S}(\mathbf{K S}) \mathbf{K}$. Then $\mathbf{B} X Y Z \triangleright_{w} X(Y Z)$ :

$$
\begin{aligned}
\mathbf{S}(\mathbf{K S}) \mathbf{K} X Y Z & \triangleright_{w} \mathbf{K S} X(\mathbf{K} X) Y Z & & \text { by } \mathbf{S}(\mathbf{K S}) \mathbf{K} X \triangleright_{1 w} \mathbf{K} \mathbf{S} X(\mathbf{K} X) \\
& \triangleright_{w} \mathbf{S}(\mathbf{K} X) Y Z & & \text { by } \mathbf{K} \mathbf{S} X \triangleright_{1 w} \mathbf{S} \\
& \triangleright_{w} \mathbf{K} X Z(Y Z) & & \text { by } \mathbf{S}(\mathbf{K} X) Y Z \triangleright_{1 w} \mathbf{K} X Z(Y Z) \\
& \triangleright_{w} X(Y Z) & & \text { by } \mathbf{K} X Z \triangleright_{1 w} X
\end{aligned}
$$

(Cp. the operator $\mathbf{B}$ mentioned earlier.)
2. It is $\mathbf{S K K} X \triangleright_{w} X$, i.e. SKK behaves as the identity operator $\mathbf{I}$ mentioned earlier. We define $\mathbf{I}: \bumpeq \mathbf{S K K}$.

## Remarks.

1. Weak reduction $\triangleright_{w}$ is invariant under substitution (cp. Lemma 1.10), i.e. it holds: If $X \triangleright_{w} Y$ and $U \triangleright_{w} V$, then $U[X / z] \triangleright_{w} V[Y / z]$.
2. The Church-Rosser property holds (cp. Theorem 1.13):

- If $X \triangleright_{w} U$ and $X \triangleright_{w} V$, then there exists a term $T$ such that $U \triangleright_{w} T$ and $V \triangleright_{w} T$.
- If $X={ }_{w} Y$, then there exists a term $T$ such that $X \triangleright_{w} T$ and $Y \triangleright_{w} T$.

### 2.2 The formal theory $\mathrm{CL} \boldsymbol{w}$

Definition 2.5 We define the formal theory $C L w$, whose formulas are all equations of the formal theory $C L w$ form $X=Y$ for CL-terms $X, Y$.

Axioms of $\mathrm{CL} w$ are all instances of the following axiom schemata:
$(K) \mathbf{K} X Y=X$
(S) $\mathbf{S} X Y Z=X Z(Y Z)$
( $\rho$ ) $X=X \quad$ (reflexivity)
The rules are:
( $\sigma$ ) $\begin{aligned} & X=Y \\ & Y=X\end{aligned} \quad$ (symmetry)
( $\tau) \frac{X=Y \quad Y=Z}{X=Z} \quad$ (transitivity)
( $\mu) \frac{X}{}=X^{\prime}{ }^{\prime}$
(v) $\begin{aligned} Y & =Y^{\prime} \\ Y X & =Y^{\prime} X\end{aligned}$

The notions derivation and proof are defined analogously to Definition 1.36, and
$\mathrm{CL} w \vdash X=Y$ means that $X=Y$ is provable in $\mathrm{CL} w$,
$\mathrm{CL} w_{\triangleright} \vdash X=Y$ means that $X=Y$ is provable in $\mathrm{CL} w$ without rule $(\sigma)$.

## Lemma 2.6

1. $X={ }_{w} Y \Longleftrightarrow C L w \vdash X=Y$.
2. $X \triangleright_{w} Y \Longleftrightarrow C L w_{\triangleright} \vdash X=Y$.

Proof. Exercise. QED

### 2.3 On the relation between $\lambda$-calculus and CL

To investigate the relation between $\lambda$-calculus and combinatory logic we consider translations of CL-terms into $\lambda$-terms and vice versa.

Definition 2.7 For a CL-term $X$ the $\lambda$-term $X_{\lambda}$ is defined as follows:

1. $x_{\lambda}: \bumpeq x$
2. $\mathbf{K}_{\lambda}: \bumpeq \lambda x y . x$
3. $\mathbf{S}_{\lambda}: \bumpeq \lambda x y z . x z(y z)$
4. $(X Y)_{\lambda}: \bumpeq X_{\lambda} Y_{\lambda}$
(We here identify congruent $\lambda$-terms; this means that $M \bumpeq N$ in case $M \equiv{ }_{\alpha} N$, for $\lambda$-terms $M, N$.)

## Lemma 2.8

1. If $X \triangleright_{w} Y$, then $X_{\lambda} \triangleright_{\beta} Y_{\lambda}$.
2. If $X={ }_{w} Y$, then $X_{\lambda}={ }_{\beta} Y_{\lambda}$.

Proof. Use $\mathrm{CL} w_{\triangleright}$ and $\lambda \beta_{\triangleright}$, resp. CL $w$ and $\lambda \beta$.

Remark. The converse direction does not hold.
For example, we have $\mathbf{S}_{\lambda} \mathbf{K}_{\lambda}={ }_{\beta} \mathbf{K}_{\lambda}\left(\mathbf{S}_{\lambda} \mathbf{K}_{\lambda} \mathbf{K}_{\lambda}\right)$, but not $\mathbf{S K}={ }_{w} \mathbf{K}(\mathbf{S K K})$. None of the CL-terms contracts, while both $\lambda$-terms contain redexes.

Definition 2.9 For a $\lambda$-term $M$ the CL-term $M_{\text {CL }}$ is defined as follows:

1. $x_{\mathrm{CL}}: \bumpeq x$
2. $(M N)_{\mathrm{CL}}: \bumpeq M_{\mathrm{CL}} N_{\mathrm{CL}}$
3. $(\lambda x . M)_{\mathrm{CL}}: \bumpeq[x] \cdot M_{\mathrm{CL}}$
where $[x] . Y$ ("abstraction $x$ dot $Y$ ") for CL-terms $Y$ is defined as follows:
4. $[x] . x: \bumpeq$ SKK (abbreviated: I $: \bumpeq \mathbf{S K K})$;
5. $[x] . Y: \bumpeq \mathbf{K} Y$, if $x \notin \mathrm{FV}(Y)$;
6. $[x] . U x: \bumpeq U$, if $x \notin \mathrm{FV}(U)$;
7. $[x] .(U V): \bumpeq \mathbf{S}([x] \cdot U)([x] . V)$, if none of the preceding cases applies.

Example. It is $[x] . x x z \bumpeq \mathbf{S}([x] \cdot x x)([x] . z) \bumpeq \mathbf{S}(\mathbf{S}([x] \cdot x)([x] . x))(\mathbf{K} z) \bumpeq \mathbf{S}(\mathbf{S I I})(\mathbf{K} z)$.

## Remarks.

1. The expression $[x] . Y$ is metalinguistic; $[x] . Y$ is not a CL-term, but only represents a CL-term.
2. It is $x \notin \mathrm{FV}([x] . Y)$. In this respect $[x]$ behaves like a variable-binding operator.

Lemma 2.10 We have $([x] . Y) Z \triangleright_{w} Y[Z / x]$.
Proof. By induction on the structure of $Y$ :

1. $Y \bumpeq x:([x] . x) Z \bumpeq \mathbf{I} Z \triangleright_{w} Z \bumpeq x[Z / x]$
2. $Y$ is an atom and $Y \neq x:([x] . Y) Z \bumpeq \mathbf{K} Y Z \triangleright_{w} Y \bumpeq Y[Z / x]$
3. $Y \bumpeq(U V)$ :
$-x \notin \mathrm{FV}(Y):([x] . Y) Z \bumpeq \mathbf{K} Y Z \triangleright_{w} Y \bumpeq Y[Z / x]$
$-x \notin \mathrm{FV}(U)$ and $V \bumpeq x:([x] . Y) Z \bumpeq U Z \bumpeq U x[Z / x]$

- none of the preceding cases:

$$
\begin{aligned}
([x] \cdot Y) Z & \bumpeq \mathbf{S}([x] \cdot U)([x] . V) Z \\
& \triangleright_{w}([x] \cdot U) Z(([x] \cdot V) Z) \\
& \triangleright_{w}(U[Z / x])(V[Z / x]) \quad \text { (induction hypothesis) } \\
& \bumpeq Y[Z / x]
\end{aligned}
$$

## Corollary 2.11 (Combinatorial completeness)

Let $V$ be a term with $\left\{x_{1}, \ldots, x_{n}\right\} \subseteq \mathrm{FV}(V)$. Then there exists a term $U$ without occurrences of $x_{1}, \ldots, x_{n}$ such that $U X_{1} \ldots X_{n} \triangleright_{w} V\left[X_{1} / x_{1}\right] \ldots\left[X_{n} / x_{n}\right]$.

Remark. Thus every combinator $U$ that is given by a "new" contraction

$$
U X_{1} \ldots X_{n} \triangleright_{w} W
$$

where $W$ is constructed from $X_{1}, \ldots, X_{n}$ only, can be defined in CL by a variable-free term.
Using only $\mathbf{S}$ and $\mathbf{K}$ we can thus express "all possible" combinators.

## Lemma 2.12

1. For CL-terms $X$ we have: $\left(X_{\lambda}\right)_{C L} \bumpeq X$.
2. For $\lambda$-terms $M$ we have: $\left(M_{C L}\right)_{\lambda}={ }_{\beta \eta} M$.

## Proof.

1. By induction on the structure of $X$ :
$-\left(x_{\lambda}\right)_{\mathrm{CL}} \bumpeq x_{\mathrm{CL}} \bumpeq x$
$-\left(\mathbf{K}_{\lambda}\right)_{\mathrm{CL}} \bumpeq(\lambda x y \cdot x)_{\mathrm{CL}} \bumpeq[x] .([y] . x) \bumpeq[x] . \mathbf{K} x \bumpeq \mathbf{K}$
$-\left(\mathbf{S}_{\lambda}\right)_{\mathrm{CL}} \bumpeq(\lambda x y z . x z(y z))_{\mathrm{CL}}$
$\bumpeq[x] .([y] \cdot([z] \cdot x z(y z)))$
$\bumpeq[x] \cdot([y] \cdot \mathbf{S}([z] \cdot x z)([z] \cdot y z))$
$\bumpeq[x] .([y] \cdot \mathbf{S} x y)$
$\bumpeq[x] . S x$
$\bumpeq S$
$-\left((U V)_{\lambda}\right)_{\mathrm{CL}} \bumpeq\left(U_{\lambda} V_{\lambda}\right)_{\mathrm{CL}} \bumpeq\left(U_{\lambda}\right)_{\mathrm{CL}}\left(V_{\lambda}\right)_{\mathrm{CL}} \bumpeq U V \quad$ (the latter by i.h.)
2. By induction on the structure of $M$ :
$-M \bumpeq x:\left(x_{\mathrm{CL}}\right)_{\lambda} \bumpeq x_{\lambda} \bumpeq x$
$-M \bumpeq(P Q)$ :
$\left((P Q)_{\mathrm{CL}}\right)_{\lambda} \bumpeq\left(P_{\mathrm{CL}} Q_{\mathrm{CL}}\right)_{\lambda} \bumpeq\left(P_{\mathrm{CL}}\right)_{\lambda}\left(Q_{\mathrm{CL}}\right)_{\lambda}={ }_{\beta \eta} P Q \quad$ (the latter by i.h.)
$-M \bumpeq\left(\lambda x \cdot M^{\prime}\right)$ : We have to show $\left(\left(\lambda x \cdot M^{\prime}\right)_{\mathrm{CL}}\right)_{\lambda} \bumpeq\left([x] \cdot\left(M^{\prime}\right)_{\mathrm{CL}}\right)_{\lambda}={ }_{\beta \eta} \lambda x \cdot M^{\prime}$.
Induction on the structure of $M^{\prime}$ :

- $\left([x] . x_{\mathrm{CL}}\right)_{\lambda} \bumpeq \mathbf{I}_{\lambda} \bumpeq \mathbf{S}_{\lambda} \mathbf{K}_{\lambda} \mathbf{K}_{\lambda}={ }_{\beta} \lambda x . x$
- if $x \notin \mathrm{FV}\left((P Q)_{\mathrm{CL}}\right)$ :

$$
\begin{aligned}
\left([x] \cdot(P Q)_{\mathrm{CL}}\right)_{\lambda} & \bumpeq\left(\mathbf{K}(P Q)_{\mathrm{CL}}\right)_{\lambda} \\
& \bumpeq \mathbf{K}_{\lambda}\left((P Q)_{\mathrm{CL}}\right)_{\lambda} \\
& \bumpeq(\lambda x y \cdot x)\left((P Q)_{\mathrm{CL}}\right)_{\lambda} \quad \text { where } y \notin \mathrm{FV}(P Q) \\
& ={ }_{\beta} \lambda y \cdot\left((P Q)_{\mathrm{CL}}\right)_{\lambda} \\
& ={ }_{\beta \eta} \lambda y \cdot(P Q) \quad \text { (induction hypothesis) }
\end{aligned}
$$

- if $x \notin \mathrm{FV}\left(P_{\mathrm{CL}}\right)$ and $Q_{\mathrm{CL}} \bumpeq x$ :

$$
\begin{aligned}
\left([x] \cdot(P Q)_{\mathrm{CL}}\right)_{\lambda} & \bumpeq\left([x] \cdot\left(P_{\mathrm{CL}} Q_{\mathrm{CL}}\right)\right)_{\lambda} \\
& \bumpeq\left([x] \cdot\left(P_{\mathrm{CL}} x\right)\right)_{\lambda} \\
& \bumpeq\left(P_{\mathrm{CL}}\right)_{\lambda} \\
& ={ }_{\beta \eta} P \quad \text { (induction hypothesis) } \\
& ={ }_{\eta} \lambda x \cdot(P x) \\
& \bumpeq \lambda x \cdot(P Q)
\end{aligned}
$$

- otherwise: $\left([x] \cdot(P Q)_{\mathrm{CL}}\right)_{\lambda} \bumpeq\left(\mathbf{S}\left([x] \cdot P_{\mathrm{CL}}\right)\left([x] \cdot Q_{\mathrm{CL}}\right)\right)_{\lambda}$

$$
\begin{aligned}
& \bumpeq \mathbf{S}_{\lambda}\left([x] \cdot P_{\mathrm{CL}}\right)_{\lambda}\left([x] \cdot Q_{\mathrm{CL}}\right)_{\lambda} \\
& ={ }_{\beta \eta} \mathbf{S}_{\lambda}(\lambda x \cdot P)(\lambda x \cdot Q) \quad \text { (induction hypothesis) } \\
& \bumpeq(\lambda u v y \cdot u y(v y))(\lambda x \cdot P)(\lambda x \cdot Q) \\
& ={ }_{\beta} \lambda y \cdot(\lambda x \cdot P) y((\lambda x \cdot Q) y) \\
& ={ }_{\beta} \lambda x \cdot(P Q) \quad \text { QED }
\end{aligned}
$$

Corollary 2.13 By Lemma 2.8 we thus have: $M_{C L}={ }_{w} N_{C L} \Longrightarrow M={ }_{\beta \eta} N$.
Remark. However, we do not have $\left(M_{\mathrm{CL}}\right)_{\lambda}={ }_{\beta} M$.
A counterexample is $\left((\lambda x . y x)_{\mathrm{CL}}\right)_{\lambda} \bumpeq([x] . y x)_{\lambda} \bumpeq y_{\lambda} \bumpeq y \neq \beta \lambda x . y x$.

## Differences between $\lambda$-calculus and CL

None of the following statements holds:

$$
\begin{array}{ll}
M_{\mathrm{CL}} \triangleright_{w} N_{\mathrm{CL}} \Longrightarrow M \triangleright_{\beta} N & M_{\mathrm{CL}} \triangleright_{w} N_{\mathrm{CL}} \Longleftarrow M \triangleright_{\beta} N \\
M_{\mathrm{CL}}=_{w} N_{\mathrm{CL}} \Longrightarrow M=_{\beta} N & M_{\mathrm{CL}}=_{w} N_{\mathrm{CL}} \Longleftarrow M={ }_{\beta} N
\end{array}
$$

Thus $\beta$-reducibility of a $\lambda$-term $M$ to a $\lambda$-term $N$ cannot be shown by using translations $(\sim)$ and weak reducibility as follows: $M \sim M_{\mathrm{CL}} \triangleright_{w} N_{\mathrm{CL}} \leadsto N$.
The problem with " $\Longrightarrow$ " is that

$$
(\eta) \quad[x] \cdot X x=X \text {, if } x \notin \operatorname{FV}(X)
$$

holds in $\mathrm{CL} w$, since we have

$$
(\lambda x \cdot M x)_{\mathrm{CL}} \bumpeq[x] \cdot M_{\mathrm{CL}} x \bumpeq M_{\mathrm{CL}}, \text { if } x \notin \mathrm{FV}(M) .
$$

The problem with " $\Longleftarrow$ " is that

$$
\text { ( } \xi) \frac{X=X^{\prime}}{[x] \cdot X=[x] \cdot X^{\prime}}
$$

does not hold in $\mathrm{CL} w$, since we have

$$
\begin{aligned}
{[x] \cdot \mathbf{S} x y z } & \bumpeq \mathbf{S}([x] \cdot \mathbf{S} x y)([x] \cdot z) \\
& \bumpeq \mathbf{S}(\mathbf{S}([x] \cdot \mathbf{S} x)([x] \cdot y))(\mathbf{K} z) \\
& \bumpeq \mathbf{S}(\mathbf{S S}(\mathbf{K} y))(\mathbf{K} z)
\end{aligned}
$$

and

$$
\begin{aligned}
{[x] \cdot x z(y z) } & \bumpeq \mathbf{S}([x] \cdot x z)([x] \cdot y z) \\
& \bumpeq \mathbf{S}(\mathbf{S}([x] \cdot x)([x] \cdot z))(\mathbf{K}(y z)) \\
& \bumpeq \mathbf{S}(\mathbf{S} \mathbf{I}(\mathbf{K} z))(\mathbf{K}(y z))
\end{aligned}
$$

Hence $\mathbf{S} x y z={ }_{w} x z(y z)$, but not $[x] . \mathbf{S} x y z={ }_{w}[x] . x z(y z)$.

## Extensionality

Adding ( $\xi$ ) to CLw yields full extensionality ( $\zeta$ ):

$$
\begin{aligned}
& (\eta) \overline{\overline{[x] \cdot X x=X}} \\
& \left.\begin{array}{ll}
(\sigma) \frac{X x=Y x}{X=[x] \cdot X x} & (\xi) \frac{X x}{[x] \cdot X x=[x] \cdot Y x} \\
(\tau) \frac{(\eta) \overline{[x] \cdot Y x=Y}}{} & \\
(\tau) \frac{X=[x] \cdot Y x}{X=Y} &
\end{array}\right)
\end{aligned}
$$

In $\lambda \beta$ : $(\xi)$ holds eo ipso, while adding $(\eta)$ yields extensionality.
In $\mathrm{CL} w$ : $(\eta)$ holds eo ipso, while adding $(\xi)$ yields extensionality.
This shows how the two systems differ.

## Strong reduction

We define strong reduction $>$ by extending $\mathrm{CL} w_{\triangleright}$ by

$$
\text { (छ) } \frac{X>-Y}{[x] \cdot X>-[x] \cdot Y}
$$

Then we have for $\lambda$-terms $M, N$ :

$$
M \triangleright_{\beta \eta} N \Longrightarrow M_{\mathrm{CL}}>N_{\mathrm{CL}}
$$

The converse direction $M_{\mathrm{CL}}>N_{\mathrm{CL}} \Longrightarrow M \triangleright_{\beta \eta} N$ does, however, not hold, since $X>Y$ does not imply $X_{\lambda} \triangleright_{\beta \eta} Y_{\lambda}$.
We only have

$$
M_{\mathrm{CL}}>N_{\mathrm{CL}} \Longrightarrow M={ }_{\beta \eta} N
$$

Now $\eta$-conversion is an instance of $(\rho)$ and holds in arbitrary directions. For $\lambda$-terms
$M, N$ we therefore have:

$$
M={ }_{\beta \eta} N \Longleftrightarrow M_{\mathrm{CL}}><N_{\mathrm{CL}}
$$

where $><$ is the symmetric closure of $>$. Then the following holds for CL-terms $X, Y$ :

$$
X><Y \Longleftrightarrow X_{\lambda}={ }_{\beta \eta} Y_{\lambda} .
$$

## Weakening of $[x]$. $Y$

In order to be able to represent $\beta$-equality (instead of only $\beta \eta$-equality) in $\mathrm{CL} w$, one can weaken the definition of $[x] . Y$ in such a way that $(\eta)$ does no longer hold automatically; for example by removing clause
3. $[x] \cdot U x: \bumpeq U$, if $x \notin \mathrm{FV}(U)$
from the definition of $[x] . Y$.
However, even in this case $(\xi)$ does not hold, since

$$
[x] . \mathbf{S} x y z \bumpeq \mathbf{S}(\mathbf{S}(\mathbf{S}(\mathbf{K S}) \mathbf{I})(\mathbf{K} y))(\mathbf{K} z)
$$

and (as before)

$$
[x] \cdot x z(y z) \bumpeq \mathbf{S}(\mathbf{S} \mathbf{I}(\mathbf{K} z))(\mathbf{K}(y z))
$$

Again, we do not have $[x] \cdot \mathbf{S} x y z={ }_{w}[x] \cdot x z(y z)$, while $\mathbf{S} x y z={ }_{w} x z(y z)$ does hold. However, using the modified definition of $[x] . Y$ one can show

$$
\begin{aligned}
\lambda \beta \vdash M & =N \\
(\mathrm{CL} w+\otimes) \vdash X=Y & \Longleftrightarrow \lambda \beta \vdash X_{\lambda}=Y_{\lambda}
\end{aligned}
$$

where $\otimes$ is an extension of $C L w$ by a certain rule schema or by a certain finite set of axioms (cp. the formal theory $\mathrm{CL} \zeta_{\beta}$ in Hindley \& Seldin (2008), Ch. 9).

## Soundness

For the modified definition of $[x]$. $Y$ we do not have $\left(\mathbf{S}_{\lambda}\right)_{\mathrm{CL}}={ }_{w} \mathbf{S}$. However, by a further modification it is possible to obtain for $=_{\beta}$ the following (instead of Lemma 2.12 for $={ }_{\beta \eta}$ ):

1. For CL-terms $X:\left(X_{\lambda}\right)_{C L} \bumpeq X$.
2. For $\lambda$-terms $M:\left(M_{C L}\right)_{\lambda}={ }_{\beta} M$.

The evaluation in CL $w$ of translated $\lambda$-terms is then sound. This fact is often used in functional programming.

## Completeness

Regarding completeness the following holds: We consider an extended language where additional functions can be evaluated (so-called $\delta$-rules). The corresponding reductions are $\triangleright_{1 \beta \delta}, \triangleright_{\beta \delta}$ and $\triangleright_{1 \beta \beta \delta}$ ( $l$ for leftmost), resp. $\triangleright_{1 w \delta}$ and $\triangleright_{w \delta}$. We then have:

If $M \triangleright_{1 / \beta \delta} N$, where $M$ is closed and does not have the form $[x] . P$, then $M_{\mathrm{CL}} \triangleright_{1 w \delta} N_{\mathrm{CL}}$.

If a second-order typed system with primitive types Int, Bool and Char is given, in which a fixed-point operator $\Upsilon$ exists and where $M$ has a primitive type, then the following holds:

$$
M \triangleright_{I \beta \delta} N \Longrightarrow M_{\mathrm{CL}} \triangleright_{w \delta} N_{\mathrm{CL}}
$$

This means that everything that can be found in $\lambda \beta$ can be found in CL $w$ by a translation. This fact is e.g. used in the functional programming language Miranda (see Turner, 1979).

For a constant $c$ with some primitive type (which by definition is in $\beta$-normal form) we thus get

$$
\begin{aligned}
\lambda \delta \vdash M=c & \Longrightarrow M={ }_{\beta \delta} c \\
& \Longrightarrow M \triangleright_{l \beta \delta} c \\
& \Longrightarrow M_{\mathrm{CL}} \triangleright_{w \delta} c \\
& \Longrightarrow \mathrm{CL} w \delta \vdash M_{\mathrm{CL}}=c
\end{aligned}
$$

as well as the converse

$$
\begin{aligned}
\mathrm{CL} w \delta \vdash M_{\mathrm{CL}}=c & \Longrightarrow M_{\mathrm{CL}}=_{w \delta} c \\
& \Longrightarrow M_{\mathrm{CL}} \triangleright_{w \delta} c \\
& \Longrightarrow \underbrace{\left(M_{\mathrm{CL}}\right)_{\lambda}}_{=\beta} \triangleright_{\beta \delta} c \\
& \Longrightarrow \lambda \beta \vdash M=c
\end{aligned}
$$

Every computation of a value for $M$ can thus also be done in $\mathrm{CL} w$.

## 3 The simply typed $\lambda$-calculus

There are two variants of typing $\lambda$-terms:

1. Curry-style typing: Terms are the terms of the untyped theory. Every term has a (possibly empty) set of possible types (implicit typing, type assignment).
2. Church-style typing: Terms have associated types, which are usually unique (explicit typing).

We consider only Curry-style typing in the following, and moreover in its most simple form that has only so-called simple types. The simply typed $\lambda$-calculus is called $\lambda \rightarrow$. We follow the treatment in Barendregt (1992). (Since we consider only the simply typed $\lambda$-calculus, we omit the specifier "simply".)

Remark. For $\lambda \rightarrow$ strong normalisability holds. Hence not all recursive functions are definable in $\lambda \rightarrow$; the partial recursive functions are not $\lambda \rightarrow$-definable at all, but there are also total recursive functions which are not definable.
We define the function $F$ as follows (for some adequate enumeration of typed terms):

$$
F(n, m)= \begin{cases}k & \begin{array}{l}
\text { iff the } n \text {-th typed term applied to the } \\
\text { argument } \underline{m} \text { has the } \beta \text {-normal form } \underline{k},
\end{array} \\
0 & \text { otherwise. }\end{cases}
$$

But then the (total) function $g(n):=F(n, n)+1$ cannot be definable in $\lambda \rightarrow$ : Let $g$ be defined in $\lambda \rightarrow$ by the $p$-th typed term. Then $g(p)=F(p, p)$; however, by definition $g(p)=F(p, p)+1$. Contradiction.

### 3.1 Implicit typing

Remarks. 1. To avoid unnecessary complications we exclude certain kinds of $\lambda$-terms, namely

- terms in which a variable occurs free as well as bound,
- (sub)terms of the form $\lambda x \cdot M$, in which $\lambda x$ occurs also in $M$.
(That is, terms like $(x(\lambda x .(\lambda x . x)))$, for example, are not considered.) Note that this is not an essential restriction of the expressive power of our language.

2. We use $\sigma, \tau, \sigma_{1}, \sigma_{2}, \ldots$ as metalinguistic variables for types.

Definition 3.1 The set of types of $\lambda \rightarrow$ is defined as follows:

1. Type variables $\alpha, \beta, \gamma, \delta, \alpha_{1}, \alpha_{2}, \ldots$ are types.
2. If $\sigma$ and $\tau$ are types, then $(\sigma \rightarrow \tau)$ is a type (also called function type).

It is $\sigma_{1} \rightarrow \sigma_{2} \rightarrow \cdots \rightarrow \sigma_{n-1} \rightarrow \sigma_{n}$ an abbreviation of $\sigma_{1} \rightarrow\left(\sigma_{2} \rightarrow\left(\cdots\left(\sigma_{n-1} \rightarrow \sigma_{n}\right) \cdots\right)\right)$; that is, we use association to the right for function types.

Curry-style typing

Church-style typing

[^1]

- A judgement has the form $M: \sigma$ for a $\lambda$-term $M$ and a type $\sigma$. The term $M$ is called the subject of the judgement. (The type $\sigma$ is then also called the predicate. One says " $M$ has type $\sigma$ " or something like that.)
- A declaration is a judgement whose subject is a term variable.
- A basis $\Gamma$ is a finite set of declarations whose subjects are pairwise distinct.
- A sequent has the form $\Gamma \vdash M: \sigma$ for a basis $\Gamma$ and a judgement $M: \sigma$.

Definition 3.2 Sequents $\Gamma \vdash M: \sigma$ expressing that the judgement $M: \sigma$ holds in basis $\Gamma$ can be derived in the calculus $\lambda \rightarrow$, which is given by the axiom scheme

$$
\text { (Id) } \Gamma, x: \sigma \vdash x: \sigma
$$

together with the following $\rightarrow$-introduction and $\rightarrow$-elimination rules:

$$
(\rightarrow \mathrm{I}) \frac{\Gamma, x: \sigma \vdash M: \tau}{\Gamma \vdash(\lambda x . M): \sigma \rightarrow \tau} \quad(\rightarrow \mathrm{E}) \frac{\Gamma \vdash M: \sigma \rightarrow \tau \quad \Gamma \vdash N: \sigma}{\Gamma \vdash(M N): \tau}
$$

If $\Gamma \vdash M: \sigma$ is derivable in $\lambda \rightarrow$, then we write $\Gamma \vdash_{\lambda \rightarrow M}: \sigma$ or $\Gamma \vdash M: \sigma$. (Thus we often identify sequents with the assertion of their derivability. What is meant in each case should be clear from the context.)

## Examples.

1. It is $\vdash_{\lambda \rightarrow} \lambda x y \cdot x: \sigma \rightarrow \tau \rightarrow \sigma$ :

$$
\begin{array}{r}
(\rightarrow \mathrm{I}) \frac{(\mathrm{Id}) \overline{x: \sigma, y: \tau \vdash x: \sigma}}{(\rightarrow \mathbf{I}) \frac{x: \sigma \vdash \lambda y \cdot x: \tau \rightarrow \sigma}{\vdash \lambda x \cdot \lambda y \cdot x: \sigma \rightarrow \tau \rightarrow \sigma}}
\end{array}
$$

That is, the combinator $\mathbf{K}$ has type $\sigma \rightarrow \tau \rightarrow \sigma$.
2. It is $\vdash_{\lambda \rightarrow} \lambda x y z . x z(y z):\left(\sigma \rightarrow \tau \rightarrow \tau^{\prime}\right) \rightarrow(\sigma \rightarrow \tau) \rightarrow \sigma \rightarrow \tau^{\prime}:$

Let $\Gamma=\left\{x: \sigma \rightarrow \tau \rightarrow \tau^{\prime}, y: \sigma \rightarrow \tau, z: \sigma\right\}$.

That is, the combinator $\mathbf{S}$ has type $\left(\sigma \rightarrow \tau \rightarrow \tau^{\prime}\right) \rightarrow(\sigma \rightarrow \tau) \rightarrow \sigma \rightarrow \tau^{\prime}$.
Remark. One can add constants. Corresponding declarations for constants are then
added to every basis. An example is the fixed-point combinator $\mathbf{Y}:(\sigma \rightarrow \sigma) \rightarrow \sigma$ for all types $\sigma$ in the programming language ML.

## Definition 3.3

- A closed term $M$ is called typable, if $\vdash M: \sigma$ for a type $\sigma$.
- A term $M$ with free variables $x_{1}, \ldots, x_{n}$ is called typable, if $\Gamma \vdash M: \sigma$ for a type $\sigma$, where $\Gamma=\left\{x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n}\right\}$ for certain types $\sigma_{1}, \ldots, \sigma_{n}$.
- Let $\Gamma=\left\{x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n}\right\}$ be a basis. Then let $\Gamma\left(x_{i}\right):=\sigma_{i}$.
- Let $V$ be a set of variables and $\Gamma$ a basis. Then the restriction of $\Gamma$ to $V$ is defined by

$$
\left.\Gamma\right|_{V}:=\{x: \sigma \mid x \in V \text { and } \Gamma(x)=\sigma\}
$$

- The domain of $\Gamma$ is $\operatorname{dom}(\Gamma):=\left\{x_{1}, \ldots, x_{n}\right\}$.
- Type substitution: $\sigma[\tau / \alpha]$ signifies the simultaneous replacement of all occurrences of the type variable $\alpha$ in type $\sigma$ by type $\tau$. (See also Definition 3.11.)
For a basis $\Gamma=\left\{x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n}\right\}$ the expression $\Gamma[\tau / \alpha]$ signifies the result of type substitutions $\sigma_{i}[\tau / \alpha]$, for $1 \leq i \leq n$, in $\Gamma$.

Remark. For sequents $\Gamma \vdash M: \sigma$ one refers to $M: \sigma$ also as a hypothetical judgement, since it depends on the basis $\Gamma$; for sequents $\vdash M: \sigma$ one refers to $M: \sigma$ as a categorical judgement.

Example. The term $x x$ is not typable. Consider

$$
(\mathrm{Id}) \frac{\overline{x: \sigma \rightarrow \tau, x: \sigma \vdash x: \sigma \rightarrow \tau}}{(\mathrm{E})} \frac{(\mathrm{Id}) \overline{x: \sigma \rightarrow \tau, x: \sigma \vdash x: \sigma}}{x: \sigma \rightarrow \tau, x: \sigma \vdash x x: \tau}
$$

This is not a correct derivation, since the subjects of the basis $\{x: \sigma \rightarrow \tau, x: \sigma\}$ are not pairwise distinct.
Consequently, $\lambda x . x x$ is not typable, since any corresponding derivation would have to begin as shown above. Hence, for example $\boldsymbol{\Omega}$ has no type as well.

## Lemma 3.4

1. If $\Gamma \subseteq \Gamma^{\prime}$ for bases $\Gamma$ and $\Gamma^{\prime}$, then $\left(\Gamma \vdash M: \sigma \Longrightarrow \Gamma^{\prime} \vdash M: \sigma\right)$. (monotony)
2. If $\Gamma \vdash M: \sigma$, then $\mathrm{FV}(M) \subseteq \operatorname{dom}(\Gamma)$.
3. If $\Gamma \vdash M: \sigma$, then $\left.\Gamma\right|_{\mathrm{FV}(M)} \vdash M: \sigma$.
4. If $\Gamma \vdash x: \sigma$, then $(x: \sigma) \in \Gamma$.
5. If $\Gamma \vdash(\lambda x . M): \sigma$, then $\sigma \bumpeq \sigma_{1} \rightarrow \sigma_{2}$ for some $\sigma_{1}, \sigma_{2}$ and $\Gamma, x: \sigma_{1} \vdash M: \sigma_{2}$.
6. If $\Gamma \vdash M N: \sigma$, then $\Gamma \vdash M: \tau \rightarrow \sigma$ and $\Gamma \vdash N: \tau$ for a $\tau$.
7. If $\Gamma \vdash M: \sigma$ and $M^{\prime}$ is subterm of $M$, then $\Gamma^{\prime} \vdash M^{\prime}: \sigma^{\prime}$ for some $\Gamma^{\prime}, \sigma^{\prime}$.
8. If $\Gamma \vdash M: \sigma$, then $\Gamma[\tau / \alpha] \vdash M: \sigma[\tau / \alpha]$.
9. If $\Gamma, x: \sigma \vdash M: \tau$ and $\Gamma \vdash N: \sigma$, then $\Gamma \vdash M[N / x]: \tau$.
10. If $\Gamma \vdash M: \sigma$ and $M \triangleright_{\beta} M^{\prime}$, then $\Gamma \vdash M^{\prime}: \sigma$. (subject reduction)

## Remarks.

1. The latter says that types are invariant under subject reduction.
2. However, invariance under subject expansion $\triangleleft_{\beta}$ does not hold; that is, if $M \triangleleft_{\beta} M^{\prime}$ and $\Gamma \vdash M: \sigma$, then in general $\Gamma \vdash M^{\prime}: \sigma$ does not hold.

Example: Although $\mathbf{I} \triangleleft_{\beta} \mathbf{K I}(\lambda x . x x)$ and $\vdash \mathbf{I}: \sigma \rightarrow \sigma$, we have $\nvdash \mathbf{K I}(\lambda x . x x): \sigma \rightarrow \sigma$.
3. Lemma 3.4 (4)-(6) is also referred to as "generation lemma" in the literature.

In the following we show that all typable terms are strongly normalising. (Weak normalisability was already shown by Turing; strong normalisability goes back to Tait, 1967.) The converse does not hold: For example, the term $\lambda x . x x$ in $\beta$-nf is not typable.

## Definition 3.5

- Let SN be the set of strongly normalisable $\lambda$-terms.
- For sets $A, B$ of $\lambda$-terms let $A \rightarrow B:=\{M \mid$ for all $N \in A$ it is $M N \in B\}$.
- The interpretation of types is defined inductively as follows:

$$
\begin{aligned}
\llbracket \alpha \rrbracket & :=\mathrm{SN}, \text { for all type variables } \alpha ; \\
\llbracket \sigma \rightarrow \tau \rrbracket & :=\llbracket \sigma \rrbracket \rightarrow \llbracket \tau \rrbracket .
\end{aligned}
$$

Remark. The interpretation of a function type is a set of $\lambda$-terms having the desired transition property $A \rightarrow B$ w.r.t. the given domain $A$ and co-domain $B$.

Definition 3.6 A set $A$ of terms is called saturated, if the following holds (for $n \geq 0$ ):
(a) $A \subseteq \mathrm{SN}$,
(b) $x R_{1} \ldots R_{n} \in A$, if $x$ is a term variable and $R_{1}, \ldots, R_{n} \in \mathrm{SN}$,
(c) $(\lambda x . M) N R_{1} \ldots R_{n} \in A$, if $(M[N / x]) R_{1} \ldots R_{n} \in A$ for $N, R_{1}, \ldots, R_{n} \in \mathrm{SN}$.

SAT $:=\{A \mid A$ saturated $\}$.
Lemma 3.7 For every type $\sigma$ of $\lambda \rightarrow$ it holds that $\llbracket \sigma \rrbracket$ is saturated.

## Proof.

1. $\sigma$ is a type variable. We have to show: SN is saturated.
(a) $\mathrm{SN} \subseteq \mathrm{SN}$.
(b) $x R_{1} \ldots R_{n} \in \mathrm{SN}$, if $R_{1}, \ldots, R_{n} \in \mathrm{SN}$.
(c) Let $(M[N / x]) R_{1} \ldots R_{n} \in \mathrm{SN}$ with $N, R_{1}, \ldots, R_{n} \in \mathrm{SN}$.

Then also $M \in \mathrm{SN}$, since otherwise $(M[N / x]) R_{1} \ldots R_{n}$ could not be strongly
normalisable. We consider $(\lambda x . M) N R_{1} \ldots R_{n}$. Then every reduction series has the following form, where $M \triangleright_{\beta} M^{\prime}, N \triangleright_{\beta} N^{\prime}$ and $R_{i} \triangleright_{\beta} R_{i}^{\prime}$ for $1 \leq i \leq n$ :

$$
\begin{gathered}
(\lambda x \cdot M) N R_{1} \ldots R_{n} \triangleright_{\beta}\left(\lambda x \cdot M^{\prime}\right) N^{\prime} R_{1}^{\prime} \ldots R_{n}^{\prime} \\
\triangleright_{1 \beta} M^{\prime}\left[N^{\prime} / x\right] R_{1}^{\prime} \ldots R_{n}^{\prime} \\
\triangleright_{\beta} \ldots
\end{gathered}
$$

We know that if $S \triangleright_{\beta} T$ and $P \triangleright_{\beta} Q$, then $P[S / x] \triangleright_{\beta} Q[T / x]$. Thus:

$$
(M[N / x]) R_{1} \ldots R_{n} \triangleright_{\beta}\left(M^{\prime}\left[N^{\prime} / x\right]\right) R_{1}^{\prime} \ldots R_{n}^{\prime} \triangleright_{\beta} \ldots
$$

Since this series terminates, the first series terminates as well.
Therefore $(\lambda x . M) N R_{1} \ldots R_{n}$ is strongly normalisable.
2. $\sigma$ is a function type $\sigma_{1} \rightarrow \sigma_{2}$. Let $A=\llbracket \sigma_{1} \rrbracket$ and $B=\llbracket \sigma_{2} \rrbracket$.

If $A$ and $B$ are saturated, then so is $A \rightarrow B$ :
(a) Let $M \in A \rightarrow B$. By Definition 3.6 (b) we have $x \in A$ for all variables $x$ (case $n=0$ ). Thus $M x \in B$. Since $M x$ is strongly normalisable, also $M$ is strongly normalisable. Therefore $A \rightarrow B \subseteq \mathrm{SN}$.
(b) Let $M \in A$. Then $M \in \mathrm{SN}$. Hence $x R_{1} \ldots R_{n} M \in B$ for $R_{i} \in \mathrm{SN}$. Thus also $x R_{1} \ldots R_{n} \in A \rightarrow B$.
(c) Let $M \in A$. Then $M \in \mathrm{SN}$.

Then $(\lambda x . P) N R_{1} \ldots R_{n} M \in B$, if $(P[N / x]) R_{1} \ldots R_{n} M \in B$.
Then $(\lambda x . P) N R_{1} \ldots R_{n} \in A \rightarrow B$, if $(P[N / x]) R_{1} \ldots R_{n} \in A \rightarrow B$.
QED

## Definition 3.8

- A valuation is a function $\rho$ : variables $\rightarrow \lambda$-terms.
valuation
interpretation
(of terms)
satisfiability
- A valuation $\rho$ satisfies $M: \sigma$, if $\llbracket M \rrbracket_{\rho} \in \llbracket \sigma \rrbracket$. Notation: $\rho \vDash M: \sigma$.
- A valuation $\rho$ satisfies a basis $\Gamma$, if $\rho \vDash x: \sigma$ for all $(x: \sigma) \in \Gamma$.

Notation: $\rho \vDash \Gamma$.

- A basis $\Gamma$ satisfies $M: \sigma$, if:

For all valuations $\rho$ : If $\rho \vDash \Gamma$, then $\rho \vDash M: \sigma$.

Notation: $\Gamma \vDash M: \sigma$.

Lemma 3.9 (Soundness) If $\Gamma \vdash M: \sigma$, then $\Gamma \vDash M: \sigma$.
Proof. By induction on the structure of the derivation of $\Gamma \vdash M: \sigma$.
Case (Id): Let $\Gamma=\Gamma^{\prime} \cup\{x: \sigma\}$ and $M \bumpeq x$. It is $\Gamma^{\prime}, x: \sigma \vdash x: \sigma$.
Suppose $\rho \vDash \Gamma^{\prime} \cup\{x: \sigma\}$, then $\rho \vDash x: \sigma$ as a special case. Hence $\Gamma^{\prime}, x: \sigma \vDash x: \sigma$.
Case $(\rightarrow \mathrm{I}):$ Let $M \bumpeq \lambda x$. $N$. Then $\sigma \bumpeq \sigma_{1} \rightarrow \sigma_{2}$ and $\Gamma, x: \sigma_{1} \vdash N: \sigma_{2}$.
By the induction hypothesis we have $\Gamma, x: \sigma_{1} \vDash N: \sigma_{2}$.
That is, if $\rho \vDash \Gamma$ and $\rho(x) \in \llbracket \sigma_{1} \rrbracket$, then $\llbracket N \rrbracket \rho \in \llbracket \sigma_{2} \rrbracket$.
Then $\llbracket(\lambda x . N) x \rrbracket_{\rho} \in \llbracket \sigma_{2} \rrbracket$, since $\llbracket \sigma_{2} \rrbracket$ is saturated.
That is, if $\rho \vDash \Gamma$ and $\rho(x)=Q \in \llbracket \sigma_{1} \rrbracket$, then $\llbracket \lambda x . N \rrbracket_{\rho} Q=\llbracket(\lambda x . N) x \rrbracket_{\rho} \in \llbracket \sigma_{2} \rrbracket$.
Hence $\llbracket \lambda x . N \rrbracket_{\rho} \in \llbracket \sigma_{1} \rightarrow \sigma_{2} \rrbracket$.
Case $(\rightarrow \mathrm{E})$ : Let $M \bumpeq P Q$. Then $\Gamma \vdash P: \tau \rightarrow \sigma$ and $\Gamma \vdash Q: \tau$.
By the induction hypothesis we have $\Gamma \vDash P: \tau \rightarrow \sigma$ and $\Gamma \vDash Q: \tau$.
That is, if $\rho \vDash \Gamma$, then $\llbracket P \rrbracket_{\rho} \in \llbracket \tau \rightarrow \sigma \rrbracket$ and $\llbracket Q \rrbracket_{\rho} \in \llbracket \tau \rrbracket$.
Then $\llbracket P Q \rrbracket_{\rho} \in \llbracket \sigma \rrbracket$ by Definition of $\llbracket \rrbracket$, since $\llbracket P Q \rrbracket_{\rho}=\llbracket P \rrbracket_{\rho} \llbracket Q \rrbracket_{\rho}$. QED
Theorem 3.10 If $\Gamma \vdash M: \sigma$, then $M$ is strongly normalisable.
Proof. Suppose $\Gamma \vdash M: \sigma$. Then by soundness $\Gamma \vDash M: \sigma$. That is, it holds for all valuations $\rho$ : If $\rho \vDash \Gamma$, then $\rho \vDash M: \sigma$.
Let $\rho_{i d}(x):=x$ for every free variable $x$ in $M$. Then $\rho_{i d} \vDash \Gamma$, since $x \in \llbracket \sigma \rrbracket$ for every $x$ (since $\llbracket \sigma \rrbracket$ is saturated). Therefore $\rho_{i d} \vDash M: \sigma$, i.e. $M \bumpeq \llbracket M \rrbracket \rho_{\rho_{i d}} \in \llbracket \sigma \rrbracket$. Since $\llbracket \sigma \rrbracket$ is saturated, $M$ is strongly normalisable.

### 3.2 The type assignment algorithm

In the following, we present an algorithm that assigns types to terms. If a given term is typable, the algorithm assigns a type; otherwise the algorithm outputs fail. This immediately solves the two most important decidability problems concerning implicit type assignment:

1. Given $M$ and $\sigma$, does $\vdash M: \sigma$ hold? (type checking)
2. Given $M$, is there a $\sigma$ with $\vdash M: \sigma$ ? (typability)

A further decidability problem is the following:
3. Given $\sigma$, is there an $M$ with $\vdash M: \sigma$ ? (type inhabitation)
type checking
typability
type inhabitation

This is solved by the Curry-Howard isomorphism (see Section 3.3).
We begin with some preliminaries on substitution and unification of type variables and types.

## Definition 3.11

- A substitution (in types) is a function $s:$ type variables $\rightarrow$ types, where $s(\alpha) \neq \alpha$ only for finitely many $\alpha$.
substitution (in types)

We write $s$ also as $\left\{\alpha_{1}=\sigma_{1}, \ldots, \alpha_{n}=\sigma_{n}\right\}$, if $s\left(\alpha_{i}\right)=\sigma_{i}$.

- Obviously, $s$ determines a function $\bar{s}$ from types to types:

$$
\begin{aligned}
\bar{s}(\alpha) & : \bumpeq s(\alpha) \\
\bar{s}(\sigma \rightarrow \tau) & : \bumpeq \bar{s}(\sigma) \rightarrow \bar{s}(\tau)
\end{aligned}
$$

We identify $s$ and $\bar{s}$ and write $s(\sigma)$ or $\sigma\left[\sigma_{1} / \alpha_{1}, \ldots, \sigma_{n} / \alpha_{n}\right]$.

- For a basis $\Gamma=\left\{x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n}\right\}$ let $s(\Gamma)=\left\{x_{1}: s\left(\sigma_{1}\right), \ldots, x_{n}: s\left(\sigma_{n}\right)\right\}$.
- For substitutions $s_{1}$ and $s_{2}$ the composition $s_{1} \circ s_{2}$ (short: $s_{1} s_{2}$ ) is defined naturally. Correspondingly, $s_{1} \circ s_{2}(\sigma) \bumpeq s_{1}\left(s_{2}(\sigma)\right)$.
- A unifier for $\sigma$ and $\tau$ is an $s$ with $s(\sigma) \bumpeq s(\tau)$.

A unifier for a set of equations $E=\left\{\sigma_{1}=\tau_{1}, \ldots, \sigma_{n}=\tau_{n}\right\}$ is an $s$ with $s\left(\sigma_{i}\right) \bumpeq s\left(\tau_{i}\right)$ for all $i$ with $1 \leq i \leq n$.

- A most general unifier ( $m g u$ ) for $\sigma$ and $\tau$ (w.r.t. $E$ ) is a unifier $s$ such that for every other unifier $s^{\prime}$ for $\sigma$ and $\tau$ (w.r.t. $E$ ) the following holds: $s^{\prime}=s_{1} \circ s$ for a substitution $s_{1}$.
We write $s=\operatorname{mgu}(\sigma, \tau)$, respectively $s=\operatorname{mgu}(E)$.
- It is $\tau$ a variant of $\sigma$, if there are $s_{1}$ and $s_{2}$ with $s_{1}(\tau) \bumpeq \sigma$ and $s_{2}(\sigma) \bumpeq \tau$.

## Examples.

1. $\alpha \rightarrow(\beta \rightarrow \alpha)$ and $\alpha \rightarrow(\beta \rightarrow \beta)$ have $\{\alpha / \beta\}$ as mgu.
2. $\beta \rightarrow(\alpha \rightarrow \beta)$ and $(\gamma \rightarrow \gamma) \rightarrow \delta$ have $\{\gamma \rightarrow \gamma / \beta, \alpha \rightarrow(\gamma \rightarrow \gamma) / \delta\}$ as mgu.

Remark. Two mgus w.r.t. the same set are always variants of each other. In this sense mgus are unique.

Theorem 3.12 There exists an algorithm (called "unification algorithm") which yields for every system of equations $E$ an $m g u$ for $E$, if $E$ is unifiable, and outputs fail, if $E$ is not unifiable.

Proof. See logic programming. One algorithm (due to Herbrand) consists of transformation rules for systems of equations $E=\left\{\sigma_{1}=\tau_{1}, \ldots, \sigma_{n}=\tau_{n}\right\}$ where $E_{1} \dot{\cup} E_{2}$ denotes the union of disjoint sets $E_{1}$ and $E_{2}$ :

$$
\text { (id) } \frac{E \dot{\cup}\{\sigma=\sigma\}}{E}
$$

(sym) $\frac{E \dot{\cup}\{\sigma=\alpha\}}{E \cup\{\alpha=\sigma\}}$ if $\sigma$ is not a type variable
(fail) $\frac{E \dot{\cup}\{\alpha=\sigma\}}{\text { fail }}$ if $\alpha$ occurs in $\sigma$
(subst) $\frac{E \dot{\cup}\{\alpha=\sigma\}}{E[\sigma / \alpha] \cup\{\alpha=\sigma\}}$ if $\alpha$ does not occur in $\sigma$ and $\alpha$ occurs in $E$
(func) $\frac{E \dot{\cup}\left\{\tau_{1} \rightarrow \tau_{2}=\sigma_{1} \rightarrow \sigma_{2}\right\}}{E \cup\left\{\tau_{1}=\sigma_{1}, \tau_{2}=\sigma_{2}\right\}}$
One can show that the application of these rules to a system of equations always terminates. The result is either fail or $\left\{\alpha_{1}=\sigma_{1}, \ldots, \alpha_{n}=\sigma_{n}\right\}$, where $\left\{\alpha_{1}=\sigma_{1}, \ldots, \alpha_{n}=\sigma_{n}\right\}$ is the mgu for $E$.

## Remarks.

1. The rule name (sym) refers to the symmetry of equations, which is made use of in the rule to shift type variables from right to left (but not the other way around).
2. In applications of (subst) we will note the respective substitutions to the right of the rule bar.

We now map sequents $\Gamma \vdash M: \sigma$ to such systems of equations $E$.

## Definition 3.13

For sequents $\Gamma \vdash M: \sigma$ the associated system of equations $E(\Gamma \vdash M: \sigma)$ is defined as follows:

1. $E(\Gamma \vdash x: \sigma):=\{\sigma=\Gamma(x)\}$,
2. $E(\Gamma \vdash \lambda x . M: \sigma):=\{\sigma=\alpha \rightarrow \beta\} \cup E(\Gamma, x: \alpha \vdash M: \beta)$ for new type variables $\alpha, \beta$,
3. $E(\Gamma \vdash M N: \sigma):=E(\Gamma \vdash M: \alpha \rightarrow \sigma) \cup E(\Gamma \vdash N: \alpha)$ for a new type variable $\alpha$.

Remark. The type assignment algorithm comprises two main steps: (1) formulate the associated system of equations $E(\Gamma \vdash M: \sigma)$; (2) apply the unification algorithm.
associated system of equations
type assignment algorithm

## Examples.

1. $E(x: \alpha \vdash x: \beta)=\{\beta=\alpha\}$
2. $E(\vdash \lambda x y \cdot x: \alpha \rightarrow \beta)=\left\{\alpha \rightarrow \beta=\alpha_{1} \rightarrow \alpha_{2}\right\} \cup E\left(x: \alpha_{1} \vdash \lambda y . x: \alpha_{2}\right)$

$$
\begin{aligned}
& =\left\{\alpha \rightarrow \beta=\alpha_{1} \rightarrow \alpha_{2}, \alpha_{2}=\alpha_{3} \rightarrow \alpha_{4}\right\} \cup E\left(x: \alpha_{1}, y: \alpha_{3} \vdash x: \alpha_{4}\right) \\
& =\left\{\alpha \rightarrow \beta=\alpha_{1} \rightarrow \alpha_{2}, \alpha_{2}=\alpha_{3} \rightarrow \alpha_{4}, \alpha_{4}=\alpha_{1}\right\}
\end{aligned}
$$

Solution:

$$
\begin{aligned}
& \quad \text { (func) } \frac{\left\{\alpha \rightarrow \beta=\alpha_{1} \rightarrow \alpha_{2}, \alpha_{2}=\alpha_{3} \rightarrow \alpha_{4}, \alpha_{4}=\alpha_{1}\right\}}{\left\{\alpha=\alpha_{1}, \beta=\alpha_{2}, \alpha_{2}=\alpha_{3} \rightarrow \alpha_{4}, \alpha_{4}=\alpha_{1}\right\}} \\
& \text { (subst) } \frac{\left\{\alpha=\alpha_{1}, \beta=\alpha_{3} \rightarrow \alpha_{4}, \alpha_{2}=\alpha_{3} \rightarrow \alpha_{4}, \alpha_{4}=\alpha_{1}\right\}}{\left\{\alpha_{3} \rightarrow \alpha_{4} / \alpha_{2}\right]} \\
& \text { (subst) } \frac{\left\{\alpha=\alpha_{1}, \beta=\alpha_{3} \rightarrow \alpha_{1}, \alpha_{2}=\alpha_{3} \rightarrow \alpha_{1}, \alpha_{4}=\alpha_{1}\right\}}{\left\{\alpha=\alpha_{1} / \alpha_{4}\right]}
\end{aligned}
$$

Therefore $\vdash \lambda x y . x: \alpha_{1} \rightarrow\left(\alpha_{3} \rightarrow \alpha_{1}\right)$.

Remark: We here started with $E(\vdash \lambda x y \cdot x: \alpha \rightarrow \beta)$ instead of $E(\vdash \lambda x y \cdot x: \sigma)$. This is not a problem in this example. However, starting with a type of a specific form might result in not finding solutions that could be found by starting with the unspecific $\sigma$. Starting with $\sigma$ is thus preferable in general.
3. $E(\vdash \lambda x . x x: \sigma)=\left\{\sigma=\alpha_{1} \rightarrow \alpha_{2}\right\} \cup E\left(x: \alpha_{1} \vdash x x: \alpha_{2}\right)$

$$
\begin{aligned}
& =\left\{\sigma=\alpha_{1} \rightarrow \alpha_{2}\right\} \cup E\left(x: \alpha_{1} \vdash x: \alpha_{3} \rightarrow \alpha_{2}\right) \cup E\left(x: \alpha_{1} \vdash x: \alpha_{3}\right) \\
& =\left\{\sigma=\alpha_{1} \rightarrow \alpha_{2}, \alpha_{3} \rightarrow \alpha_{2}=\alpha_{1}, \alpha_{1}=\alpha_{3}\right\}
\end{aligned}
$$

Attempted solution:

$$
\begin{aligned}
&(\text { sym }) \frac{\left\{\sigma=\alpha_{1} \rightarrow \alpha_{2}, \alpha_{3} \rightarrow \alpha_{2}=\alpha_{1}, \alpha_{3}=\alpha_{1}\right\}}{\left\{\sigma=\alpha_{1} \rightarrow \alpha_{2}, \alpha_{1}=\alpha_{3} \rightarrow \alpha_{2}, \alpha_{3}=\alpha_{1}\right\}} \\
&(\text { subst }) \frac{\left\{\sigma=\left(\alpha_{3} \rightarrow \alpha_{2}\right) \rightarrow \alpha_{2}, \alpha_{1}=\alpha_{3} \rightarrow \alpha_{2}, \alpha_{3}=\alpha_{3} \rightarrow \alpha_{2}\right\}}{\text { fail }}\left[\alpha_{3} \rightarrow \alpha_{2} / \alpha_{1}\right] \\
&(\text { fail })
\end{aligned}
$$

The system of equations cannot be solved, since $\alpha_{3}=\alpha_{3} \rightarrow \alpha_{2}$ blocks termination. Hence, the term $\lambda x . x x$ is not typable.

## Lemma 3.14 (Soundness and completeness)

1. Let $s$ be a solution to $E(\Gamma \vdash M: \sigma)$. Then $s(\Gamma) \vdash M: s(\sigma)$ holds.
2. If $s(\Gamma) \vdash M: s(\sigma)$, then the following holds: There exists an $s^{\prime}$ which interprets the type variables in $\Gamma$ and $\sigma$ like $s$, and $s^{\prime}$ is a solution to $E(\Gamma \vdash M: \sigma)$. Type variables which are interpreted differently by $s$ and $s^{\prime}$ can always be chosen from a fixed set of type variables $V$ with $V \cap \mathrm{FV}(\Gamma \cup\{\sigma\})=\emptyset$.

## Proof.

1. Induction on the structure of $M$ :

Case $M \bumpeq x$ : The substitution $s$ is a solution to $E(\Gamma \vdash x: \sigma)$, i.e. $s(\sigma)=s(\Gamma(x))$.
Hence $x: s(\sigma)$ occurs in $s(\Gamma)$. Therefore $s(\Gamma) \vdash x: s(\sigma)$.
Case $M \bumpeq \lambda x$. $P:$ If $s$ is a solution to $E(\Gamma \vdash \lambda x . P: \sigma)$, then $s$ is a solution to

$$
\{\sigma=\alpha \rightarrow \beta\} \cup E(\Gamma, x: \alpha \vdash P: \beta) .
$$

By the induction hypothesis $s(\Gamma), x: s(\alpha) \vdash P: s(\beta)$ holds. Therefore

$$
s(\Gamma) \vdash \lambda x . P:(s(\alpha) \rightarrow s(\beta))=s(\sigma)
$$

holds.
Case $M \bumpeq P Q:$ If $s$ is a solution to $E(\Gamma \vdash P Q: \sigma)$, then $s$ is a solution to

$$
E(\Gamma \vdash P: \alpha \rightarrow \sigma) \quad \text { and } \quad E(\Gamma \vdash Q: \alpha) .
$$

By the induction hypothesis we have

$$
s(\Gamma) \vdash P: s(\alpha \rightarrow \sigma) \quad \text { and } \quad s(\Gamma) \vdash Q: s(\alpha) .
$$

Therefore $s(\Gamma) \vdash P Q: s(\sigma)$ holds.
2. Induction on the structure of $M$ :

Case $M \bumpeq x$ : It is $s(\Gamma) \vdash x: s(\sigma)$, i.e. $(x: s(\sigma)) \in s(\Gamma)$. Hence $s(\sigma)=s(\Gamma(x))$ holds.
Thus $s$ itself is a solution to $E(\Gamma \vdash x: \sigma)$.
Case $M \bumpeq \lambda x . P:$ It is $s(\Gamma) \vdash \lambda x . P: s(\sigma)$, i.e. $s(\sigma)=\sigma_{1} \rightarrow \sigma_{2}$ for certain $\sigma_{1}, \sigma_{2}$, and it is $s(\Gamma), x: \sigma_{1} \vdash P: \sigma_{2}$.
Let $s^{\prime}$ be similar to $s$, but extended by $\alpha_{1} \mapsto \sigma_{1}$ and $\alpha_{2} \mapsto \sigma_{2}$ with new $\alpha_{1}, \alpha_{2}$. Then $s^{\prime}(\Gamma), x: \alpha_{1} \vdash P: s^{\prime}\left(\alpha_{2}\right)$.
Hence $s$ and $s^{\prime}$ coincide for all type variables occurring in $\Gamma$ and $\sigma$, and $s^{\prime}$ is a solution to $\left\{\sigma=\alpha_{1} \rightarrow \alpha_{2}\right\}$.
By the induction hypothesis there exists a solution $s^{\prime \prime}$ to $E\left(\Gamma, x: \alpha_{1} \vdash P: \alpha_{2}\right)$ such that $s^{\prime \prime}$ coincides with $s^{\prime}$ for all type variables in $\Gamma, \alpha_{1}, \alpha_{2}$.
Moreover, we can assume that type variables which are interpreted differently by $s^{\prime}$ and $s^{\prime \prime}$ do not occur in $\sigma$, i.e. $s^{\prime}(\sigma)=s^{\prime \prime}(\sigma)$.
Hence $s^{\prime \prime}$ also solves $\left\{\sigma=\alpha_{1} \rightarrow \alpha_{2}\right\} \cup E\left(\Gamma, x: \alpha_{1} \vdash P: \alpha_{2}\right)$, i.e. $E(\Gamma \vdash \lambda x . P: \sigma)$, and $s^{\prime \prime}$ coincides with $s$ for all type variables in $\Gamma$ and $\sigma$.
Case $M \bumpeq P Q$ : It is $s(\Gamma) \vdash P Q: \sigma$, i.e. $s(\Gamma) \vdash P: \tau \rightarrow s(\sigma)$ and $s(\Gamma) \vdash Q: \tau$ for some $\tau$.

We define $s^{\prime}$ as $s$, extended by $\alpha \mapsto \tau$, where $\alpha$ is new. Then $s^{\prime}$ coincides with $s$ for all type variables in $\Gamma$ and $\sigma$. We thus have $s^{\prime}(\Gamma) \vdash P: s^{\prime}(\alpha) \rightarrow s^{\prime}(\sigma)$ and $s^{\prime}(\Gamma) \vdash Q: s^{\prime}(\alpha)$.
By the induction hypothesis there exist solutions $s_{1}^{\prime \prime}$ and $s_{2}^{\prime \prime}$ to $E(\Gamma \vdash P: \alpha \rightarrow \sigma)$ and $E(\Gamma \vdash Q: \alpha)$, respectively, which coincide with $s^{\prime}$ for all type variables in $\Gamma, \sigma, \alpha$. Moreover, we can assume that new type variables introduced in the construction of $E(\Gamma \vdash P: \alpha \rightarrow \sigma)$ and $E(\Gamma \vdash Q: \alpha)$ are different to each other.

Then $s_{1}^{\prime \prime} \cup s_{2}^{\prime \prime}$ is a solution to $E(\Gamma \vdash P: \alpha \rightarrow \sigma) \cup E(\Gamma \vdash Q: \alpha)$, i.e. to $E(\Gamma \vdash P Q: \sigma)$, and it coincides with $s$ on all type variables in $\Gamma$ and $\sigma$. QED

In $\lambda \rightarrow$ different types can be assigned to a given typable term. However, all such types are substitution instances of a so-called principal type.

## Definition 3.15

- We call $\sigma$ a principal type for a closed term $M$, if the following holds: If $\vdash M: \sigma$ and $\vdash M: \sigma^{\prime}$, then there exists a substitution $s$ such that $\sigma^{\prime}=s(\sigma)$.
- We call $\langle\Gamma, \sigma\rangle$ a principal pair for $M$, if the following holds: If $\Gamma \vdash M: \sigma$ and $\Gamma^{\prime} \vdash M: \sigma^{\prime}, \quad$ principal pair then there exists a substitution $s$ such that $\sigma^{\prime}=s(\sigma)$ and $\Gamma^{\prime} \supseteq s(\Gamma)$.

## Examples.

1. $\alpha \rightarrow \alpha$ is a principal type of $\mathbf{I}$.
2. $\langle\{x:(\alpha \rightarrow \alpha) \rightarrow \beta\}, \beta\rangle$ is a principal pair for $x \mathbf{I}$.

Theorem 3.16 There exists an algorithm which yields for every closed term M a principal type and for every open (or closed) term $M$ a principal pair, if $M$ is typable at all, and which outputs fail otherwise.

Proof. We consider arbitrary terms $M$. The result for closed terms is then a special case for the empty basis.
Let $\Gamma_{0}:=\left\{x_{1}: \alpha_{1}, \ldots, x_{n}: \alpha_{n}\right\}$ and $\sigma_{0}:=\beta$, where $x_{1}, \ldots, x_{n}$ are the free variables in $M$. Every mgu-solution to $E\left(\Gamma_{0} \vdash M: \sigma_{0}\right)$ is a principal pair for $M$, if there exists a solution; otherwise we get output fail.

1. $M$ has a type $\Longleftrightarrow \Gamma \vdash M: \sigma$ for certain $\Gamma, \sigma$
$\Longleftrightarrow s\left(\Gamma_{0}\right) \vdash M: s\left(\sigma_{0}\right)$ for a certain $s$
$\Longleftrightarrow E\left(\Gamma_{0} \vdash M: \sigma_{0}\right)$ is solvable (Lemma 3.14)
2. Let $s$ be an mgu-solution to $E\left(\Gamma_{0} \vdash M: \sigma_{0}\right)$. Then $s\left(\Gamma_{0}\right) \vdash M: s\left(\sigma_{0}\right)$.

Let now $\Gamma^{\prime} \vdash M: \sigma^{\prime}$ and $\widetilde{\Gamma}:=\left.\Gamma^{\prime}\right|_{\mathrm{FV}(M)}$. Then $\widetilde{\Gamma} \vdash M: \sigma^{\prime}$.
Choose $s^{\prime}$ such that $s^{\prime}\left(\Gamma_{0}\right)=\widetilde{\Gamma}$, and $s^{\prime}\left(\sigma_{0}\right)=\sigma^{\prime}$. Then $s^{\prime}\left(\Gamma_{0}\right) \vdash M: s^{\prime}\left(\sigma_{0}\right)$.
Then by Lemma 3.14 (2) the following holds for some $s^{\prime \prime}$ which interprets the type variables in $\Gamma_{0}$ and $\sigma_{0}$ like $s^{\prime}: s^{\prime \prime}$ is a solution to $E\left(\Gamma_{0} \vdash M: \sigma_{0}\right)$.
Since $s$ is an mgu, we have $s^{\prime \prime}=s_{1} \circ s$ for some $s_{1}$, i.e. $\sigma^{\prime}=s^{\prime \prime}\left(\sigma_{0}\right)=s_{1}\left(s\left(\sigma_{0}\right)\right)$.
Moreover, we have that $\Gamma \supseteq \widetilde{\Gamma}$ with $\widetilde{\Gamma}=s^{\prime \prime}\left(\Gamma_{0}\right)=s_{1}\left(s\left(\Gamma_{0}\right)\right)$.
Hence $\left\langle s\left(\Gamma_{0}\right), s\left(\sigma_{0}\right)\right\rangle$ is a principal pair for $M$.
QED

## Theorem 3.17

1. Typability is decidable.
2. Type checking is decidable.

## Proof.

1. Let a closed term $M$ be given. The algorithm of Theorem 3.16 outputs a principal type $\sigma$, if $M$ is typable, otherwise fail.
2. To check whether $\vdash M: \sigma^{\prime}$ for a given $\sigma^{\prime}$ we apply the algorithm of Theorem 3.16 to $M$. If $M$ has a type, then we obtain a type assignment $\vdash M: \sigma$ with principal type $\sigma$. Since $\sigma$ is principal, there must then be a substitution $s$ such that $\sigma^{\prime}=s(\sigma)$, if $\sigma^{\prime}$ is a type of $M$. Whether there is such a substitution $s$ can be checked by a simple algorithm.

QED

Theorem 3.18 Type inhabitation is decidable.

Proof. There is a term $M$ with $\vdash M: \sigma$ iff there is a proof of $\sigma$ (as formula) in positive implication logic. This follows from the Curry-Howard isomorphism (see the next section). Since positive implication logic is decidable, type inhabitation is decidable as well. QED

### 3.3 The Curry-Howard isomorphism

There is a certain correspondence between typed $\lambda$-calculus and logic, which can be roughly described as follows:

| Typed $\lambda$-calculus | Logic |
| :--- | :--- |
| type | formula, proposition |
| typable open term | derivation with assumptions |
| typable closed term | proof (derivation without assumptions) |
| $\beta$-contraction | contraction of derivation |
| typable term in $\beta$-normal form | derivation in normal form |
| $\beta$-equality | equality of derivations |

## Definition 3.19

- Type variables are also called propositional variables, types also (implicational) formulas.
- A finite set of formulas is called context.

Metalinguistic variables for contexts are $\Delta, \Delta^{\prime}, \ldots$

- Positive implication logic $P \rightarrow$ is given by the axiom scheme
(Id) $\Delta, \sigma \vdash \sigma$
and the two rules:

$$
(\rightarrow \mathrm{I}) \frac{\Delta, \sigma \vdash \tau}{\Delta \vdash \sigma \rightarrow \tau} \quad(\rightarrow \mathrm{E}) \frac{\Delta \vdash \sigma \rightarrow \tau \quad \Delta \vdash \sigma}{\Delta \vdash \tau}
$$

( $P \rightarrow$ is called positive implication logic, since negation does not occur.)
$-\Delta \vdash_{P \rightarrow \sigma}$ means that $\Delta \vdash \sigma$ is derivable in $P \rightarrow$.

- For a judgement $M: \sigma$ let $(M: \sigma)^{\circ} \bumpeq \sigma$.
- For a basis $\Gamma=\left\{x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n}\right\}$ let $\Gamma^{\circ}$ be the context $\left\{\sigma_{1}, \ldots, \sigma_{n}\right\}$.

Lemma 3.20 If $\Gamma \vdash_{\lambda \rightarrow} M: \sigma$, then $\Gamma^{\circ} \vdash_{P \rightarrow} \sigma$.
Proof. By application of ${ }^{\circ}$ to every judgement in the $\lambda \rightarrow$-derivation of $\Gamma \vdash M: \sigma$ one obtains a $P \rightarrow$-derivation of $\Gamma^{\circ} \vdash \sigma$.

QED
Lemma 3.21 There exists an algorithm which yields for every typable term $M$ a derivation of $\Delta \vdash \sigma$ in $P \rightarrow$ such that $\Delta=\Gamma^{\circ}$ and $\Gamma \vdash_{\lambda \rightarrow M}: \sigma$.

Proof. The algorithm mentioned in Theorem 3.16 can generate for every typable term $M$ its principal pair $\langle\Gamma, \sigma\rangle$; this can then be transformed directly into a $P \rightarrow$-sequent $\Delta \vdash \sigma$ with $\Delta=\Gamma^{\circ}$. The $P \rightarrow$-rule application necessary to derive this sequent in the last step is always determined by the form of $M$.

QED
This means: Every typable term $M$ encodes a derivation in $P \rightarrow$. From this derivation one can obtain by substitution all derivations of $\Gamma^{\circ} \vdash \sigma$ in $P \rightarrow$ which correspond to derivations of $\Gamma \vdash M: \sigma$ in $\lambda \rightarrow$.

Lemma 3.22 For every derivation of $\Delta \vdash \sigma$ in $P \rightarrow$ one can construct a term $M$ and $a$ derivation of $\Gamma \vdash M: \sigma$ in $\lambda \rightarrow$ such that $\Gamma^{\circ}=\Delta$.

Proof. Induction on the structure of the derivation of $\Delta \vdash \sigma$ in $P \rightarrow$ (where $\Delta=$ $\left.\left\{\sigma_{1}, \ldots, \sigma_{n}\right\}\right)$ :
Case (Id): All formulas $\sigma$ occurring in instances of (Id) of $P \rightarrow$ are replaced by type declarations $x: \sigma$. The variable $x$ is chosen in such a way that

- all occurrences of a formula $\sigma$ have the same corresponding declaration $x: \sigma$;
- different formulas $\sigma$ and $\tau$ have corresponding declarations $x: \sigma$ and $y: \tau$ with different variables $x$ and $y$.

Case $(\rightarrow \mathbf{I})$ : The derivation in $P \rightarrow$ ends with

$$
(\rightarrow \mathbf{I}) \frac{\sigma_{1}, \ldots, \sigma_{n}, \sigma \vdash \tau}{\sigma_{1}, \ldots, \sigma_{n} \vdash \sigma \rightarrow \tau}
$$

For the premiss $\sigma_{1}, \ldots, \sigma_{n}, \sigma \vdash \tau$ there is by the induction hypothesis a derivation in $\lambda \rightarrow$ of $x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n}, x: \sigma \vdash M: \tau$. We extend this derivation by an application of $(\rightarrow \mathbf{I})$ in $\lambda \rightarrow$ to obtain $x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n} \vdash \lambda x . M: \sigma \rightarrow \tau$.

Case $(\rightarrow \mathrm{E})$ : The derivation in $P \rightarrow$ ends with

$$
(\rightarrow \mathrm{E}) \frac{\sigma_{1}, \ldots, \sigma_{n} \vdash \sigma \rightarrow \tau \quad \sigma_{1}, \ldots, \sigma_{n} \vdash \sigma}{\sigma_{1}, \ldots, \sigma_{n} \vdash \tau}
$$

For the premisses $\sigma_{1}, \ldots, \sigma_{n} \vdash \sigma \rightarrow \tau$ and $\sigma_{1}, \ldots, \sigma_{n} \vdash \sigma$ there are by the induction hypothesis derivations in $\lambda \rightarrow$ of

$$
x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n} \vdash M: \sigma \rightarrow \tau \quad \text { and } \quad x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n} \vdash N: \sigma
$$

Note that each type $\sigma_{i}$ is assigned to exactly one variable $x_{i}$. By an application of $(\rightarrow \mathrm{E})$ we thus obtain a derivation in $\lambda \rightarrow$ of $x_{1}: \sigma_{1}, \ldots, x_{n}: \sigma_{n} \vdash M N: \tau$.

QED

## Theorem 3.23 (Curry-Howard isomorphism)

Let $M_{P}$ be the derivation in $P \rightarrow$ which corresponds to a term $M$ typable in $\lambda \rightarrow$, as given by Lemma 3.21. Let $\Pi_{\lambda}$ be the $\lambda \rightarrow$-term which corresponds to a derivation $\Pi$ in $P \rightarrow$, as given by Lemma 3.22. Then the following holds:

1. $\left(\Pi_{\lambda}\right)_{P}$ is a derivation in $P \rightarrow$ from which we can obtain $\Pi$ by substitution of formulas for propositional variables.
2. $\left(M_{P}\right)_{\lambda}$ is (modulo the renaming of free and/or bound variables) a term which results from $M$ by identification of free or bound variables.

Proof. By Lemmas 3.21 and 3.22.
QED
An example for (2) is the $\lambda$-term

$$
u(z x)(z y)
$$

for which the type assignment algorithm yields

$$
u: \alpha \rightarrow \alpha \rightarrow \beta, z: \gamma \rightarrow \alpha, x: \gamma, y: \gamma \vdash_{\lambda \rightarrow} u(z x)(z y): \beta
$$

For $\Gamma=\{u: \alpha \rightarrow \alpha \rightarrow \beta, z: \gamma \rightarrow \alpha, x: \gamma, y: \gamma\}$ we have $\Gamma^{\circ}=\{\alpha \rightarrow \alpha \rightarrow \beta, \gamma \rightarrow \alpha, \gamma\}$. The corresponding derivation $(u(z x)(z y))_{P}$ in $P \rightarrow$

$$
(\rightarrow \mathrm{E}) \frac{(\mathrm{Id}) \frac{(\mathrm{Id}) \overline{\Gamma^{\circ} \vdash \alpha \rightarrow(\alpha \rightarrow \beta)}}{(\rightarrow \mathrm{E}) \frac{\Gamma^{\circ} \vdash \gamma \rightarrow \alpha}{\Gamma^{\circ} \vdash \alpha}}(\mathrm{Id}) \overline{\Gamma^{\circ} \vdash \gamma}}{(\rightarrow \mathrm{E}) \frac{\Gamma^{\circ} \vdash \alpha \rightarrow \beta}{\Gamma^{\circ} \vdash \beta}} \quad\left(\begin{array}{ll}
(\rightarrow \mathrm{E}) \frac{\overline{\Gamma^{\circ} \vdash \gamma \rightarrow \alpha}}{\Gamma^{\circ} \vdash \alpha} & (\mathrm{Id}) \overline{\Gamma^{\circ} \vdash \gamma} \\
\end{array}\right.
$$

yields

$$
\alpha \rightarrow \alpha \rightarrow \beta, \gamma \rightarrow \alpha, \gamma \vdash_{P \rightarrow} \beta .
$$

According to Lemma 3.22, a $\lambda$-term of the form $u(z x)(z x)$, where $x$ and $y$ are identified, corresponds to this derivation.
The reason for this identification of variables is that information is lost in going from $\lambda \rightarrow$ to $P \rightarrow$, which cannot be regained by going from $P \rightarrow$ to $\lambda \rightarrow$. Note that by Lemma 3.22 the mapping of variables to formulas (= types) in instances of (Id) of $\lambda \rightarrow$ can never result in two variables having the same type. That is, by going from $\lambda \rightarrow$ to $P \rightarrow$ a sequent of the form $\Gamma, x: \sigma, y: \sigma \vdash M: \tau$ cannot occur.
In view of this loss of information one might prefer the weaker term correspondence instead of isomorphism. However, for a variant of natural deduction this loss of information can be avoided (see Troelstra \& Schwichtenberg, 2001, Ch. 6; cp. also Sørensen \& Urzyczyn, 2006, Ch. 4).

The Curry-Howard isomorphism induces reducibility and equality relations for derivations which correspond to $\triangleright_{\beta}$ and $=_{\beta}$. These relations are investigated in proof theory, most prominently on the basis of the calculus of natural deduction (see Prawitz 2006).

Consider the $\beta$-redex $(\lambda x . M) N$ with type $\tau$ :

$$
\begin{array}{cc}
\mathscr{D}_{1} \\
(\rightarrow \mathrm{I}) & \frac{\Gamma, x: \sigma \vdash M: \tau}{\Gamma \vdash \lambda x \cdot M: \sigma \rightarrow \tau} \\
(\rightarrow \mathrm{E}) & \frac{\mathscr{D}_{2}}{\Gamma \vdash(\lambda x . M) N: \tau}
\end{array}
$$

It is

$$
(\lambda x . M) N \triangleright_{1 \beta} M[N / x]
$$

To this there corresponds a contraction $\triangleright_{1 \beta}^{\circ}$ for derivations in natural deduction:

$$
\begin{array}{lllc}
{[\sigma]^{n}} & & \\
\mathscr{D}_{1}^{\circ} & & \mathscr{D}_{2}^{\circ} \\
\frac{\tau^{\sigma}}{\sigma \rightarrow \tau}(\rightarrow \mathbf{I})^{n} & \mathscr{D}_{2}^{\circ} & \sigma^{\circ} \\
\tau & \triangleright_{1 \beta}^{\circ} & \sigma \\
\frac{\sigma}{\circ} & & \mathscr{D}_{1}^{\circ}
\end{array}
$$

where all occurrences of the assumption $\sigma$ which are discharged by $(\rightarrow \mathbf{I})$ are replaced by copies of the derivation ending with $\sigma$ :

$$
\begin{gathered}
\mathscr{D}_{2}^{\circ} \\
\sigma
\end{gathered}
$$

If there are no such occurrences, then the derivation is transformed into

$$
\begin{gathered}
\mathscr{D}_{1}^{\circ} \\
\tau
\end{gathered}
$$

The replacement of all occurrences of the assumption $\sigma$ corresponds to the replacement of all occurrences of $x$ in $M$ by $N$, i.e. to the substitution $M[N / x]$.
Normalisability of $\lambda$-terms corresponds to normalisability of derivations in natural deduction and vice versa. If two derivations have the same normal form, then they are equal in the sense of $\beta$-equality.
The left derivation represents an argumentation in which a lemma of the form $\sigma \rightarrow \tau$ is used. This lemma does no longer occur in the right, contracted derivation. Normalisability of derivations ensures that by using a lemma only those things can be shown that could also be shown directly, i.e. without the lemma. This justifies the use of lemmas, which allows in general for shorter derivations.

## 4 The polymorphic typed $\lambda$-calculus

The polymorphic typed $\lambda$-calculus is also called System $F$ or typed $\lambda$-calculus of 2 nd order, short: $\lambda 2$.
Motivation: For example, the identity function $i d \bumpeq \lambda x . x: \alpha \rightarrow \alpha$ should be independent of a special type $\alpha$. That is, one would like to have $i d \bumpeq \lambda x . x: \forall \alpha .(\alpha \rightarrow \alpha)$.

## Definition 4.1

- The set of types of $\lambda 2$ is defined as follows:

1. Type variables $\alpha, \beta, \gamma, \delta, \alpha_{1}, \alpha_{2}, \ldots$ are types.
2. If $\sigma$ and $\tau$ are types, then $(\sigma \rightarrow \tau)$ is a type (called function type).
3. If $\alpha$ is a type variable and $\sigma$ is a type, then $\forall \alpha . \sigma$ is a type (called universal
types
type variables
function type
universal type
bound
free type variable
type assignment
derivable

## Examples.

1. It is $\vdash_{\lambda 2} \lambda x . x: \forall \alpha .(\alpha \rightarrow \alpha)$ :

It is also $\vdash_{\lambda 2} \lambda x . x: \forall \alpha . \alpha \rightarrow \forall \beta . \beta$ and $\vdash_{\lambda 2} \lambda x \cdot x: \forall \beta .(\forall \alpha \cdot \alpha \rightarrow \beta)$.
2. It is $\vdash_{\lambda 2} \lambda x y . y: \forall \alpha . \forall \beta .(\alpha \rightarrow(\beta \rightarrow \beta))$ :

$$
\begin{gathered}
(\mathrm{Id}) \overline{x: \alpha, y: \beta \vdash y: \beta} \\
(\rightarrow \mathbf{I}) \frac{1}{x: \alpha \vdash \lambda y \cdot y: \beta \rightarrow \beta} \\
(\rightarrow \mathbf{I}) \frac{\vdash \lambda x y \cdot y: \alpha \rightarrow(\beta \rightarrow \beta)}{\vdash \lambda} \\
(\forall \mathbf{I}) \frac{\vdash \lambda x y \cdot y: \forall \beta \cdot(\alpha \rightarrow(\beta \rightarrow \beta))}{\vdash \lambda x y \cdot y: \forall \alpha \cdot \forall \beta \cdot(\alpha \rightarrow(\beta \rightarrow \beta))}
\end{gathered}
$$

3. It is $\vdash_{\lambda 2} \lambda x . x x: \forall \beta .(\forall \alpha . \alpha \rightarrow \beta)$ :

$$
\begin{gathered}
(\mathrm{Id}) \frac{\overline{x: \forall \alpha \cdot \alpha \vdash x: \forall \alpha \cdot \alpha}}{(\forall \mathrm{E}) \frac{1}{x: \forall \alpha \cdot \alpha \vdash x: \alpha \rightarrow \beta}[\alpha \rightarrow \beta / \alpha] \quad(\forall \mathrm{E}) \frac{(\mathrm{Id})}{\frac{x: \forall \alpha \cdot \alpha \vdash x: \forall \alpha \cdot \alpha}{x: \forall \alpha \cdot \alpha \vdash x: \alpha}}[\alpha / \alpha]} \\
(\rightarrow \mathrm{E}) \frac{(\rightarrow \mathrm{I}) \frac{x: \forall \alpha \cdot \alpha \vdash x x: \beta}{\vdash \lambda x \cdot x x: \forall \alpha \cdot \alpha \rightarrow \beta}}{(\forall \mathrm{I}) \frac{\vdash \lambda x \cdot x x: \forall \beta \cdot(\forall \alpha \cdot \alpha \rightarrow \beta)}{\vdash \lambda}}
\end{gathered}
$$

It is also $\vdash_{\lambda 2} \lambda x . x x: \forall \beta .(\forall \alpha . \alpha \rightarrow(\beta \rightarrow \beta))$ and $\vdash_{\lambda 2} \lambda x . x x: \forall \alpha . \alpha \rightarrow \forall \beta . \beta$.
Definition 4.3 We define a transition relation $\sigma \sqsupset \tau$ and its transitive closure $\sigma \sqsupseteq \tau$ as
transition relation follows:

- Let $\sigma \sqsupset \tau$ (" $\sigma$ transitions into $\tau "$ ), if

$$
\tau \bumpeq \forall \alpha . \sigma \text { for a type variable } \alpha \quad(\tau \text { is a generalisation of } \sigma),
$$

or

$$
\sigma \bumpeq \forall \alpha \cdot \sigma_{1} \text { and } \tau \bumpeq \sigma_{1}\left[\sigma_{2} / \alpha\right] \text { for a type } \sigma_{2} \quad(\tau \text { is a specialisation of } \sigma) .
$$

- Let $\sigma \sqsupseteq \tau$ iff there are $n \geq 0$ such that $\sigma \bumpeq \sigma_{1} \sqsupset \cdots \sqsupset \sigma_{n} \bumpeq \tau$.

## Remarks.

1. The relation $\sqsupset$ is not symmetric:

It holds that if $\sigma \sqsupset \forall \alpha . \sigma$, then $\forall \alpha . \sigma \sqsupset \sigma$. But if $\forall \alpha . \sigma_{1} \sqsupset \sigma_{1}\left[\sigma_{2} / \alpha\right]$, then in general we do not have $\sigma_{1}\left[\sigma_{2} / \alpha\right] \sqsupset \forall \alpha . \sigma_{1}$.
2. Intuitively, $\sigma \sqsupseteq \tau$ means that $\Gamma \vdash M: \tau$ is derivable from $\Gamma \vdash M: \sigma$ by applications of $\forall$-rules only.

Lemma 4.4 Let $\Gamma$ be given. Then $\sigma \sqsupseteq \tau$ for $\sigma \bumpeq \sigma_{1} \sqsupset \cdots \sqsupset \sigma_{n} \bumpeq \tau$, where no type variable occurring free in $\Gamma$ is generalised in a step from $\sigma_{i}$ to $\sigma_{i+1}$, iff there is a (sub-) derivation of the following form:

$$
\left.\begin{array}{c}
\Gamma \vdash M: \sigma \\
\vdots \\
\Gamma \vdash M: \tau
\end{array}\right\} \text { only } \forall \text {-rules. }
$$

Proof. Definition of $\sqsupseteq$.
QED

## Lemma 4.5

1. If $\Gamma \vdash x: \sigma$, then there is a type $\sigma^{\prime}$ with $\sigma^{\prime} \sqsupseteq \sigma$ such that $\left(x: \sigma^{\prime}\right) \in \Gamma$.
2. If $\Gamma \vdash \lambda x . M: \xi$, then there are types $\sigma$ and $\tau$ such that $\Gamma, x: \sigma \vdash M: \tau$ and $(\sigma \rightarrow \tau) \sqsupseteq \xi$.
3. If $\Gamma \vdash M N: \tau$, then there are $\sigma$ and $\tau^{\prime}$ with $\tau^{\prime} \sqsupseteq \tau$ such that $\Gamma \vdash M: \sigma \rightarrow \tau^{\prime}$ and $\Gamma \vdash N: \sigma$.
4. If $\Gamma, x: \sigma \vdash M: \tau$ and $\Gamma \vdash N: \sigma$, then $\Gamma \vdash M[N / x]: \tau$.

Remark. Cp. Lemma 3.4 (4)-(6) and (9). The other assertions in Lemma 3.4 hold for $\lambda 2$ as well.

We will prove subject reduction (cp. Lemma 3.4, 10) in the following.
Definition 4.6 Let $\sigma^{0}$ be the type $\sigma$ without quantifier prefix (i.e. initial quantifiers are discarded).

## Examples.

1. $\left(\forall \alpha_{1} \ldots . \forall \alpha_{n}, \sigma\right)^{0} \bumpeq \sigma$
2. $(\forall \alpha \cdot(\forall \beta . \beta \rightarrow \alpha))^{0} \bumpeq \forall \beta \cdot \beta \rightarrow \alpha$

Lemma 4.7 If $(\sigma \rightarrow \tau) \sqsupseteq\left(\sigma^{\prime} \rightarrow \tau^{\prime}\right)$, then $\left(\sigma^{\prime} \rightarrow \tau^{\prime}\right) \bumpeq s(\sigma \rightarrow \tau)$ for a substitution s, i.e. $\sigma^{\prime} \rightarrow \tau^{\prime}$ is more special than $\sigma \rightarrow \tau$.

Proof. Let $(\sigma \rightarrow \tau) \bumpeq \sigma_{1} \sqsupset \cdots \sqsupset \sigma_{n} \bumpeq\left(\sigma^{\prime} \rightarrow \tau^{\prime}\right)$.
We show: $\sigma_{i}^{0} \bumpeq s_{i}(\sigma \rightarrow \tau)$ for every $s_{i}(1 \leq i \leq n)$.
This implies the lemma, since $\left(\sigma^{\prime} \rightarrow \tau^{\prime}\right)^{0} \bumpeq\left(\sigma^{\prime} \rightarrow \tau^{\prime}\right)$.
Proof by induction on $n$ :
For $n=1: s_{1}$ is the empty substitution.
For $n=m+1$ : Let $\sigma_{m}^{0} \bumpeq s_{m}(\sigma \rightarrow \tau)$.

- Let $\sigma_{m+1} \bumpeq \forall \alpha . \sigma_{m}$. Then $\sigma_{m+1}^{0} \bumpeq \sigma_{m}^{0}$, i.e. $s_{m+1}:=s_{m}$.
- Let $\sigma_{m} \bumpeq \forall \alpha . \rho$ and $\sigma_{m+1} \bumpeq \rho\left[\rho_{1} / \alpha\right]$. Then let $s_{m+1}:=s_{m}\left[\rho_{1} / \alpha\right]$, where $s_{m}\left[\rho_{1} / \alpha\right]$ differs from $s_{m}$ only by $\alpha \mapsto \rho_{1}$.

QED

Theorem 4.8 (Subject reduction) If $\Gamma \vdash M: \sigma$ and $M \triangleright_{\beta} M^{\prime}$, then $\Gamma \vdash M^{\prime}: \sigma$.
Proof. We consider the case $M \bumpeq(\lambda x . P) Q \triangleright_{1 \beta} P[Q / x] \bumpeq M^{\prime}$. From this the rest follows.

Suppose $\Gamma \vdash(\lambda x . P) Q: \sigma$ holds.
By Lemma 4.5 (3) there are then types $\tau$ and $\sigma^{\prime}$ with $\sigma^{\prime} \sqsupseteq \sigma$ such that

$$
\Gamma \vdash \lambda x . P: \tau \rightarrow \sigma^{\prime} \quad \text { and } \quad \Gamma \vdash Q: \tau
$$

By Lemma $4.5(2)$ there are then types $\tau$ and $\sigma^{\prime} \sqsupseteq \sigma$ as well as types $\tau^{\prime}$ and $\sigma^{\prime \prime}$ such that

$$
\Gamma, x: \tau^{\prime} \vdash P: \sigma^{\prime \prime} \quad \text { and } \quad \Gamma \vdash Q: \tau
$$

with $\left(\tau^{\prime} \rightarrow \sigma^{\prime \prime}\right) \sqsupseteq\left(\tau \rightarrow \sigma^{\prime}\right)$.
By Lemma 4.7 there is then a type $\tau$ and $\sigma^{\prime} \sqsupseteq \sigma$ such that

$$
\Gamma, x: \tau \vdash P: \sigma^{\prime} \quad \text { and } \quad \Gamma \vdash Q: \tau
$$

where $\tau$ and $\sigma^{\prime}$ are more special than $\tau^{\prime}$ and $\sigma^{\prime \prime}$, respectively.
By Lemma 4.5 (4) there is thus a type $\sigma^{\prime} \sqsupseteq \sigma$ such that $\Gamma \vdash P[Q / x]: \sigma^{\prime}$.
By Lemma 4.4 therefore $\Gamma \vdash P[Q / x]: \sigma$.
QED
Next we will prove that every term typable in $\lambda 2$ is strongly normalisable.

## Definition 4.9

- A valuation in SAT is a function $v:$ type variables $\rightarrow$ SAT.
- We define a semantics of types relative to valuations $v ; A$ is a set of terms:

1. $\llbracket \alpha \rrbracket_{v}:=v(\alpha)$,
2. $\llbracket \sigma \rightarrow \tau \rrbracket_{v}:=\llbracket \sigma \rrbracket_{v} \rightarrow \llbracket \tau \rrbracket_{v}$,
3. $\llbracket \forall \alpha, \sigma \rrbracket_{v}:=\bigcap_{A \in \mathrm{SAT}} \llbracket \sigma \rrbracket_{v[\alpha \mapsto A]}$.

Lemma 4.10 For every type $\sigma$ and every valuation $v$ it holds that $\llbracket \sigma \rrbracket_{v}$ is saturated ( $c p$. Lemma 3.7).

Proof. Analogously to the proof of Lemma 3.7. It remains to show that SAT is closed under intersection; but this is trivial. QED

Definition 4.11 We define satisfiability as follows, where for valuations $\rho$ and interpretasatisfiability tions $\llbracket M \rrbracket_{\rho}$ of terms Definition 3.8 applies:

1. $\rho, v \vDash M: \sigma: \Longleftrightarrow \llbracket M \rrbracket_{\rho} \in \llbracket \sigma \rrbracket_{v}$;
2. $\rho, v \vDash \Gamma: \Longleftrightarrow \rho, v \vDash x: \sigma$ for all $(x: \sigma) \in \Gamma$;
3. $\Gamma \vDash M: \sigma: \Longleftrightarrow$ For all valuations $\rho, v$ it holds: If $\rho, v \vDash \Gamma$, then $\rho, v \vDash M: \sigma$.

Lemma 4.12 (Soundness) If $\Gamma \vdash M: \sigma$, then $\Gamma \vDash M: \sigma$.
Theorem 4.13 If $\Gamma \vdash M: \sigma$, then $M$ is strongly normalisable.
Proof. Suppose $\Gamma \vdash M: \sigma$. Then by soundness $\Gamma \vDash M: \sigma$ holds. That is, for all valuations $\rho, v$ it holds: If $\rho, v \vDash \Gamma$, then $\rho, v \vDash M: \sigma$.
Since $\llbracket \sigma \rrbracket_{v}$ is saturated for every valuation $v$, we have $\rho_{i d}, v \vDash \Gamma$ for every valuation $v$, where $\rho_{i d}(x):=x$ for every variable $x$. Hence $\rho_{i d}, v \vDash M: \sigma$ holds, i.e. $M \in \llbracket \sigma \rrbracket_{v}$. Therefore $M$ is strongly normalisable. QED

## Remarks.

1. For $\lambda 2$ the problems of typability, type checking and type inhabitation are undecidable.
2. $\lambda 2$ has more typable terms than $\lambda \rightarrow$.

The term $\lambda x \cdot x x$ is an example of a strongly normalisable term which is not typable in $\lambda \rightarrow$ but which is typable in $\lambda 2$.
3. Is typability in $\lambda 2=$ normalisability?

No. However, every term in normal form is typable in $\lambda 2$; i.e. for every term $M$ in normal form the following holds:
$x_{1}: \forall \alpha . \alpha, \ldots, x_{n}: \forall \alpha . \alpha \vdash M: \sigma$ for a type $\sigma$, where $x_{1}, \ldots, x_{n}$ are free variables in $M$.
4. But it is strong normalisability $=$ typability in $\lambda \cap($ System $D)$.

There are no universal types in $\lambda \cap$, but so-called intersection types $\sigma \cap \tau$, for which the following type assignment rules hold:
$(\cap \mathrm{I}) \frac{\Gamma \vdash M: \sigma \quad \Gamma \vdash M: \tau}{\Gamma \vdash M: \sigma \cap \tau}$
$(\cap \mathrm{E}) \frac{\Gamma \vdash M: \sigma \cap \tau}{\Gamma \vdash M: \sigma}$
$(\cap \mathrm{E}) \frac{\Gamma \vdash M: \sigma \cap \tau}{\Gamma \vdash M: \tau}$

Thus $M: \sigma \cap \tau$ expresses that $M$ has both type $\sigma$ and type $\tau$.
It is $\vdash_{\lambda \cap} \lambda x . x x:((\sigma \rightarrow \tau) \cap \sigma) \rightarrow \tau:$

$$
\begin{aligned}
& \text { (Id) } \overline{x:(\sigma \rightarrow \tau) \cap \sigma \vdash x:(\sigma \rightarrow \tau) \cap \sigma} \\
& (\cap \mathrm{E}) \frac{(\mathrm{Id}) \overline{x:(\sigma \rightarrow \tau) \cap \sigma \vdash x:(\sigma \rightarrow \tau) \cap \sigma}}{x:(\sigma \rightarrow \tau) \cap \sigma \vdash x: \sigma \rightarrow \tau} \\
& (\rightarrow \mathrm{E}) \frac{(\cap \mathrm{E}) \frac{x:(\sigma \rightarrow \tau) \cap \sigma \vdash x: \sigma}{x}}{(\rightarrow \mathrm{I}) \frac{x:(\sigma \rightarrow \tau) \cap \sigma \vdash x x: \tau}{\vdash \lambda x . x x:((\sigma \rightarrow \tau) \cap \sigma) \rightarrow \tau}}
\end{aligned}
$$
