Keeping our Minds on Moving Pictures

Tübingen neuroscientists find neural activity in the brain is harder to disrupt when we are aware of it

Tübingen, 22 October 2013

We consciously perceive just a small part of the information processed in the brain – but which information in the brain remains unconscious and which reaches our consciousness remains a mystery. However, neuroscientists Natalia Zaretskaya and Andreas Bartels from the Centre for Integrative Neuroscience (CIN) at the University of Tübingen have now come one step closer to answering this question.

Their research, published in *Current Biology*, used a well-known visual illusion known as ‘binocular rivalry’ as a technique to make visual images invisible. Eyes usually both see the same image – binocular rivalry happens when each eye is shown an entirely different image. Our brains cannot then decide between the alternatives, and our perception switches back and forth between the images in a matter of seconds. The two images are ‘rivals’ for our attention, and every few seconds they take turns to enter our consciousness.

Using this approach the two scientists used a moving and a static picture to cause perceptual alternations in their test subjects’ minds. Simultaneously they applied magnetic pulses to disturb brain processing in a ‘motion area’ that specifically processes visual motion. The effect was unexpected: ‘zapping’ activity in the motion area did not have any effect on how long the moving image was perceived – instead, the amount of time the static image was perceived grew longer.

So ‘zapping’ the motion area while the mind was unconsciously processing motion meant that it took longer for it to become conscious of the moving image. When the moving image was being perceived, however, zapping had no effect.

This result suggests that there is a substantial difference between conscious and unconscious motion representation in the brain. Whenever motion is unconscious, its neural representation can easily be disturbed, making it difficult for it to gain the upper hand in the rivalry. However, once it becomes conscious it apparently becomes more resistant to disturbance, so that introducing noise has no effect. Therefore, one

correlate of conscious neural codes may be a more stable and noise-resistant representation of the outside world, which raises the question of how this neural stability is achieved.

The University of Tübingen

Innovative. Interdisciplinary. International. Since 1477. These have always been the University of Tübingen's guiding principles in research and teaching. With its long tradition, Tübingen is one of Germany's most respected universities. Tübingen's Neuroscience Excellence Cluster, Empirical Education Research Graduate School and institutional strategy are backed by the German government's Excellence Initiative, making Tübingen one of eleven German universities with the title of excellence. Tübingen is also home to five Collaborative Research Centers, participates in six Transregional Collaborative Research Centers, and hosts six Graduate Schools.

Our core research areas include: integrative neuroscience, clinical imaging, translational immunology and cancer research, microbiology and infection research, biochemistry and pharmaceuticals research, the molecular biology of plants, geo-environment research, astro- and elementary particle physics, quantum physics and nanotechnology, archeology and prehistory, history, religion and culture, language and cognition, media and education research.

The excellence of our research provides optimal conditions for students and academics from all over the world. Nearly 28,000 students are currently enrolled at the University of Tübingen. As a comprehensive research University, we offer more than 250 subjects. Our courses combine teaching and research, promoting a deeper understanding of the material while encouraging students to share their own knowledge and ideas. This philosophy gives Tübingen students strength and confidence in their fields and a solid foundation for interdisciplinary research.

The Werner Reichardt Centre for Integrative Neuroscience (CIN)

The Werner Reichardt Centre for Integrative Neuroscience (CIN) is an interdisciplinary institution at the University of Tübingen funded by the DFG's German Excellence Initiative program. Its aim is to deepen our understanding of how the brain generates functions and how brain diseases impair them, guided by the conviction that any progress in understanding can only be achieved through an integrative approach spanning multiple levels of organization.
