

## 7th set GAUSS assignments Financial Econometrics

---

Add all additional procedures in your personal procedure file.

### 1. Scaling factors

- i) Write additional procedures to estimate the CAPM with scaled factors. In the GAUSS file `cay.fmt` you find the instrument used by Lettau/Ludvigson (JPE 2001). To replicate the results of Lettau/Ludvigson, use the 25 Fama/French portfolios provided in `ff_25.fmt`, the market return provided in `mkret_11.fmt` and the T-bill rate provided in `tbill_11.fmt`. The stochastic discount factor is specified as:

$$m_{t+1} = a_1 + a_2 \text{cay}_t + b_1 R^m + b_2 (R_{t+1}^m \times \text{cay}_t)$$

The moment conditions are collected in a vector  $g_T(b)$ :

$$g_T(b) = \begin{bmatrix} E[m_{t+1} R_{t+1}^{e,1}] \\ \vdots \\ E[m_{t+1} R_{t+1}^{e,10}] \end{bmatrix}$$

Hint: If excess returns are used you need an additional moment restriction to identify the parameters. This moment restriction follows directly from the fact that  $E(mR^F) = 1$ .

- ii) 1. Estimate the CAPM with scaled factors for the Cochrane deciles. Scale the factors with the two instruments term spread and dividend/price ratio provided in `instruments.fmt`. Provide unconditional estimates as in i). The stochastic discount factor is specified as :

$$m_{t+1} = a_1 + b_1 R^m + b_2 (R_{t+1}^m \times d/p) + b_3 (R_{t+1}^m \times \text{term})$$

Note, that the constant is not scaled by the instruments (hence, the constant is not time varying), since Cochrane does not include the instruments themselves as factors. The moment conditions for unconditional estimates of the scaled factor model are again:

$$g_T(b) = \begin{bmatrix} E[m_{t+1} R_{t+1}^{e,1}] \\ \vdots \\ E[m_{t+1} R_{t+1}^{e,10}] \end{bmatrix}$$

2. To replicate the results in Cochrane (JPE 1996), you have to provide conditional estimates of the scaled model (use only return decile 1, 2, 5 and 10 together with the "managed portfolios"  $R^{e,i} z^i$ ). The stochastic discount factor is specified as before in 1. The moment conditions for conditional estimates of the scaled factor model are now (as

in the managed portfolio case):

$$g_T(b) = \begin{bmatrix} E[m_{t+1}R_{t+1}^{e,1}] \\ \vdots \\ E[m_{t+1}R_{t+1}^{e,10}] \\ E[(m_{t+1}R_{t+1}^{e,1})z_t^1] \\ \vdots \\ E[(m_{t+1}R_{t+1}^{e,10})z_t^1] \\ E[(m_{t+1}R_{t+1}^{e,1})z_t^2] \\ \vdots \\ E[(m_{t+1}R_{t+1}^{e,10})z_t^2] \end{bmatrix}$$

where  $z_t^1$  is the term spread and  $z_t^2$  is the dividend/price ratio.

## 2. Plot the average excess return vs. predicted excess return

Modify your procedure which returns the series for the stochastic discount factor to account for the different specifications of the SDF in part 1 of this assignment sheet and produce the plot fitted return vs. realized return.
